

## Chapter 4:

# Implementing High Availability and Redundancy in a Campus Network

- CCNP-RS SWITCH

# Chapter 4 Objectives

- Understand high availability.
- Implement high availability.
- Describe high availability monitoring options.
- Describe switch supervisor redundancy.
- Describe gateway redundancy protocols.
- Configure and verify Cisco IOS server load balancing.

# Understanding High Availability

# Components of High Availability

- Redundancy
- Technology (including hardware and software features)
- People
- Processes
- Tools

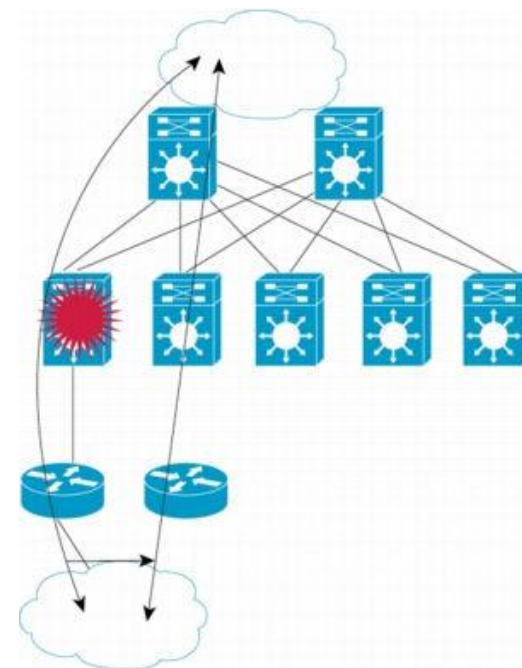

# Redundancy

- Geographic diversity and path diversity are often included.
- Dual devices and links are common.
- Dual WAN providers are common.
- Dual data centers are sometimes used, especially for large companies and large e-commerce sites.
- Dual collocation facilities, dual phone central office facilities, and dual power substations can be implemented.

# Technology

- Cisco Nonstop Forwarding (NSF)
- Stateful Switchover (SSO)
- Graceful Restart
- Cisco IOS IP Service Level Agreements (SLA)
- Object Tracking
- Firewall Stateful Failover

# People

- Prepare, Plan, Design, Implement, Operate, and Optimize (PPDIOO) is a guide.
- Work habits and attention to detail important.
- Skills are acquired via ongoing technical training.
- Good communication and documentation critical.
- Use lab testing to simulate failover scenarios.
- Take time to design.
- Identify roles.
- Identify responsibilities.
- Align teams with services.
- Ensure time to do job.

# Processes

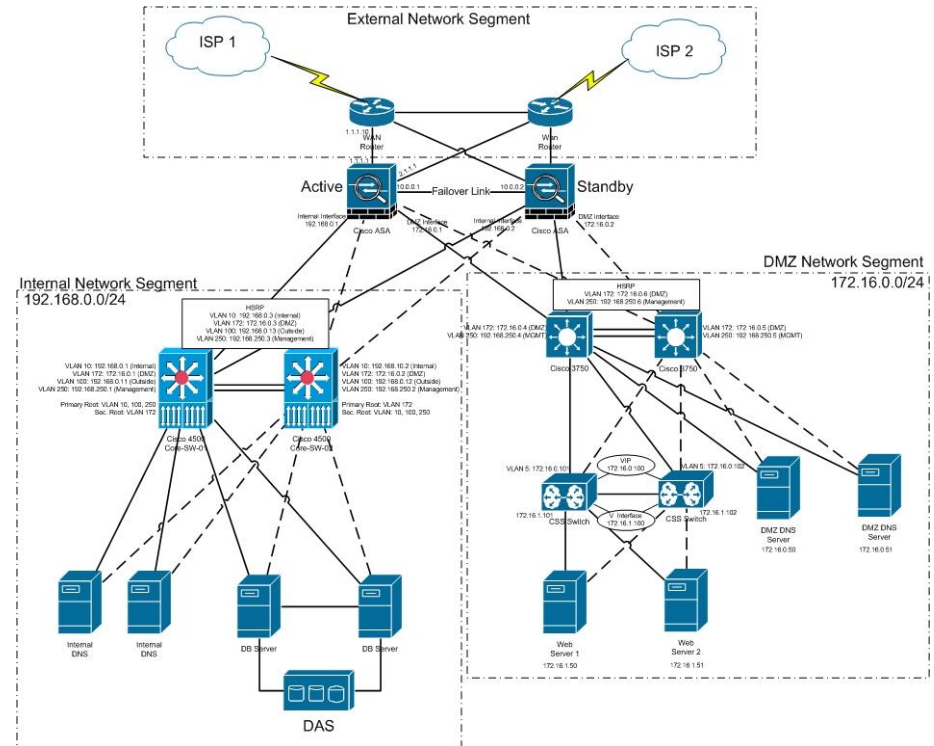

- Organizations should build repeatable processes.
- Organizations should use labs appropriately.
- Organizations need meaningful change controls.
- Management of operational changes is important.

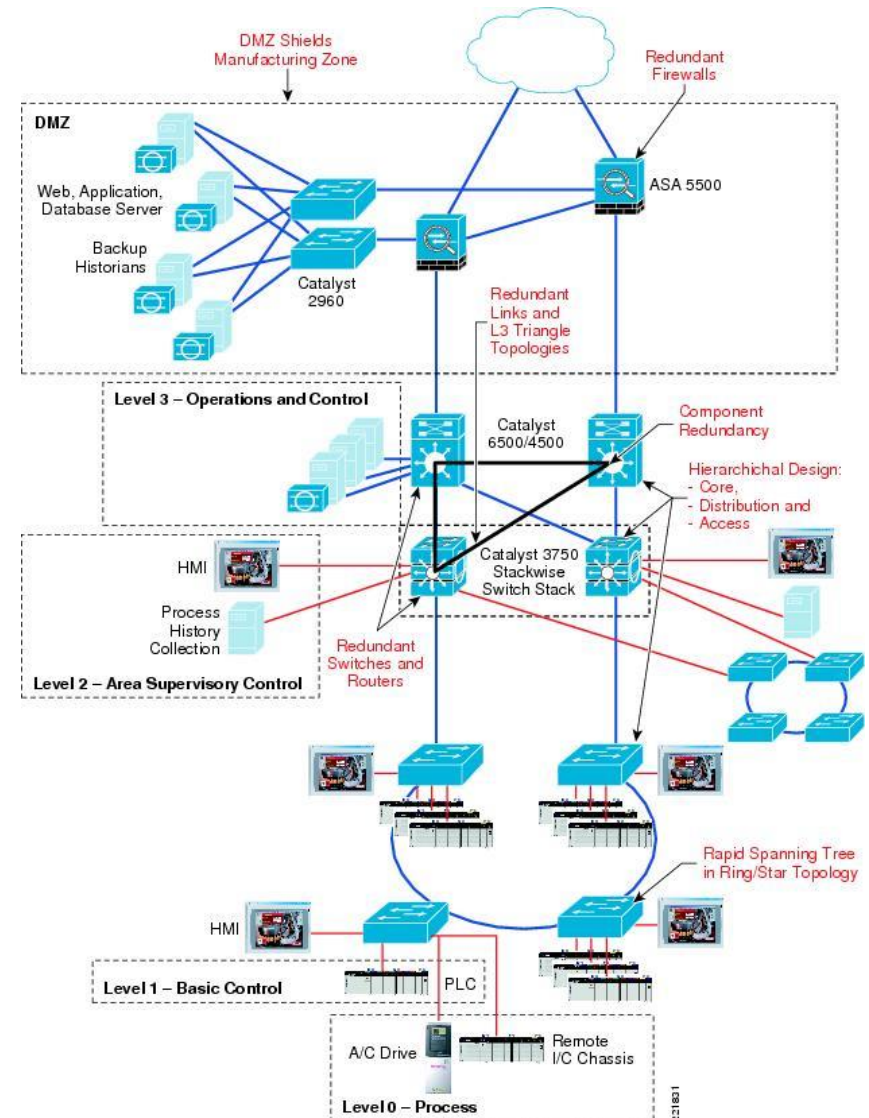

# Tools

- Network diagrams.
- Documentation of network design evolution.
- Key addresses, VLANs, and servers documented.
- Documentation tying services to applications and physical servers.

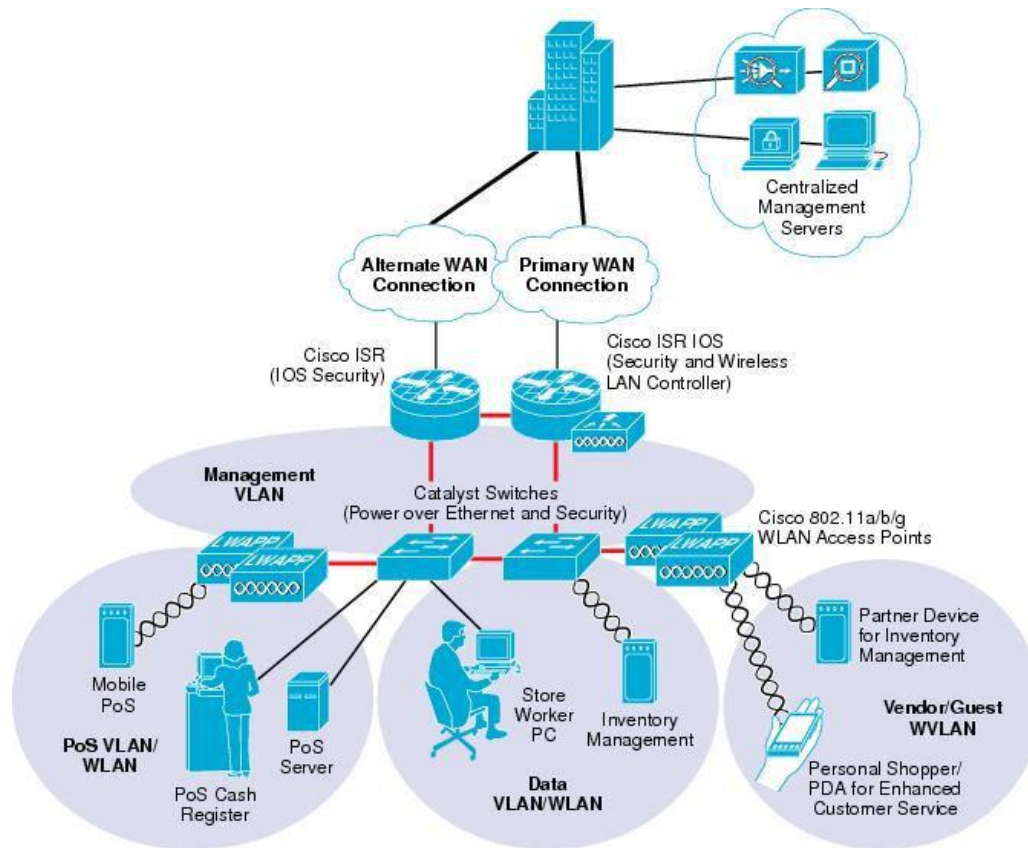

# Resiliency for High Availability

- Network-Level Resiliency
- High Availability and Failover Times

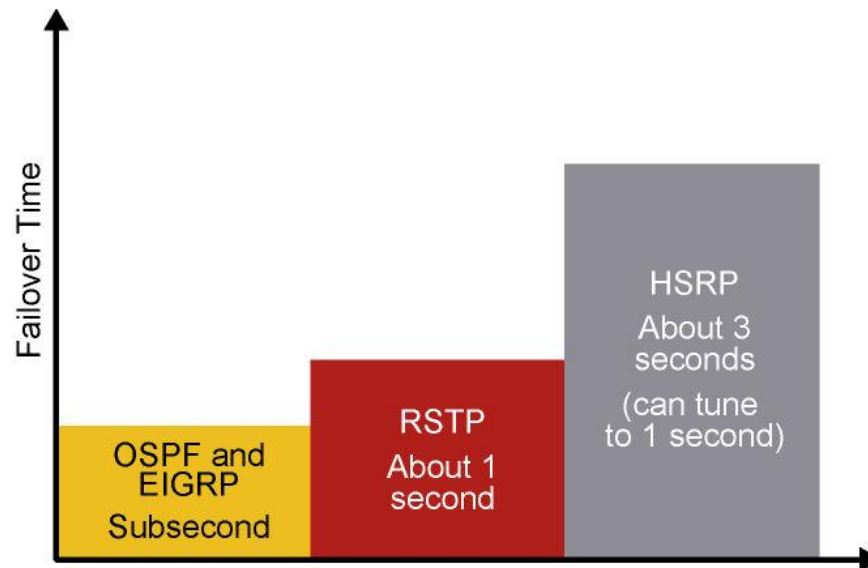

# Network-Level Resiliency

- Built with device and link redundancy.
- Employs fast convergence.
- Relies on monitoring with NTP, SNMP, Syslog, and IP SLA.

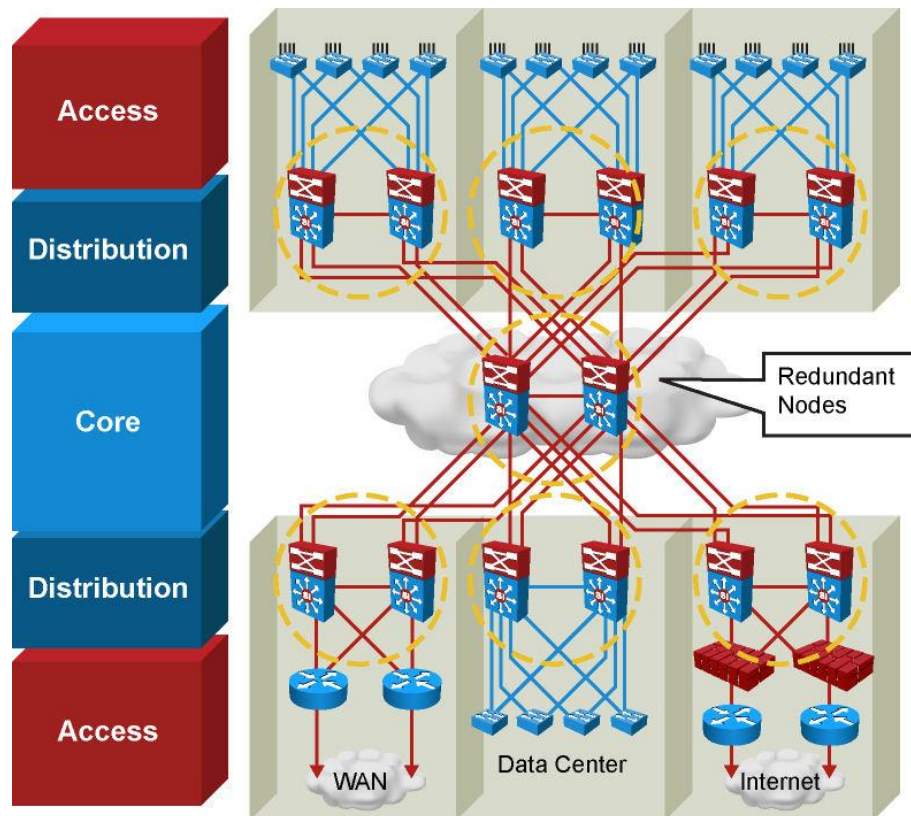

# High Availability and Failover Times

- Tuned routing protocols failover in less than 1 second.
- RSTP converges in about 1 second.
- EtherChannel can failover in approximately 1 second.
- HSRP timers are 3 seconds for hello and 10 seconds for hold time.
- Stateful service modules typically failover within 3-5 seconds.
- TCP/IP stacks have up to a 9-second tolerance.

# Optimal Redundancy

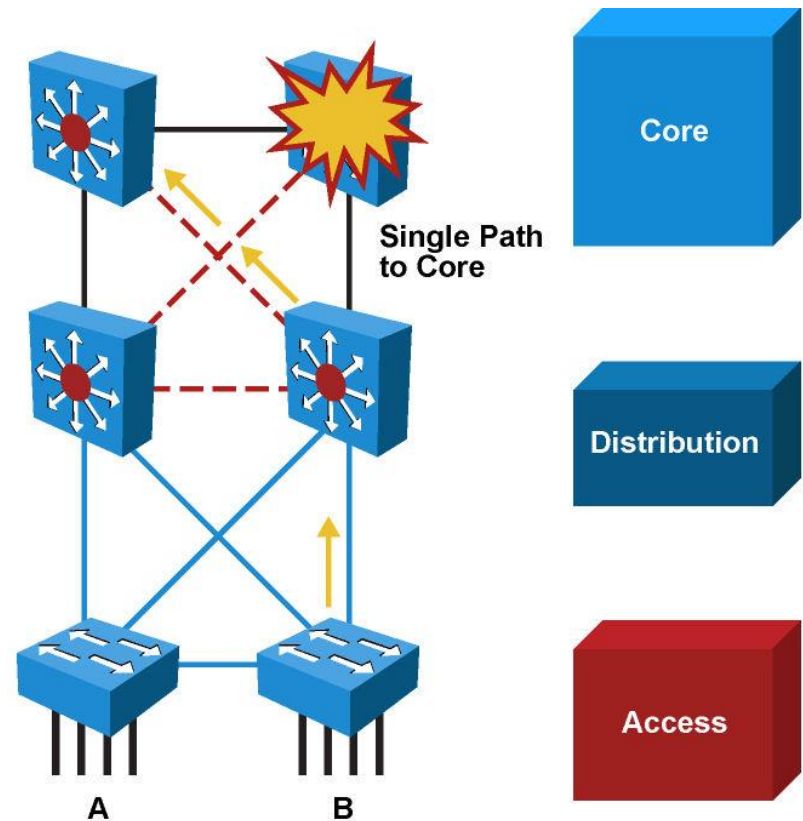

- Provide alternate paths.
- Avoid too much redundancy.
- Avoid single point of failure.
- Use Cisco NSF with SSO, if applicable.
- Use Cisco NSF with routing protocols.

334P\_432

# Provide Alternate Paths

- Use redundant distribution-to-core links in case a core switch fails.
- Link distribution switches to support summarization of routing information from the distribution to the core.

# Avoid Too Much Redundancy

- Where should the root switch be placed? With this design, it is not easy to determine where the root switch is located.
- What links should be in a blocking state? It is hard to determine how many ports will be in a blocking state.
- What are the implications of STP and RSTP convergence? The network convergence is definitely not deterministic.
- When something goes wrong, how do you find the source of the problem? The design is much harder to troubleshoot.

# Avoid Single Point of Failure

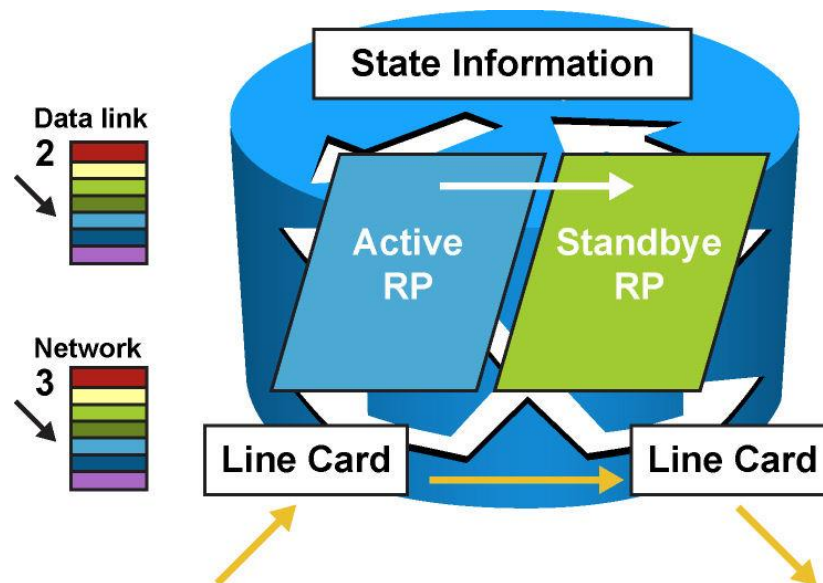

- Key element of high availability.
- Easy to implement at core and distribution.
- Access layer switch is single point of failure. Reduce outages to 1 to 3 seconds in the access layer with:
  - SSO in L2 environment
  - Cisco NSF with SSO in L3 environment.

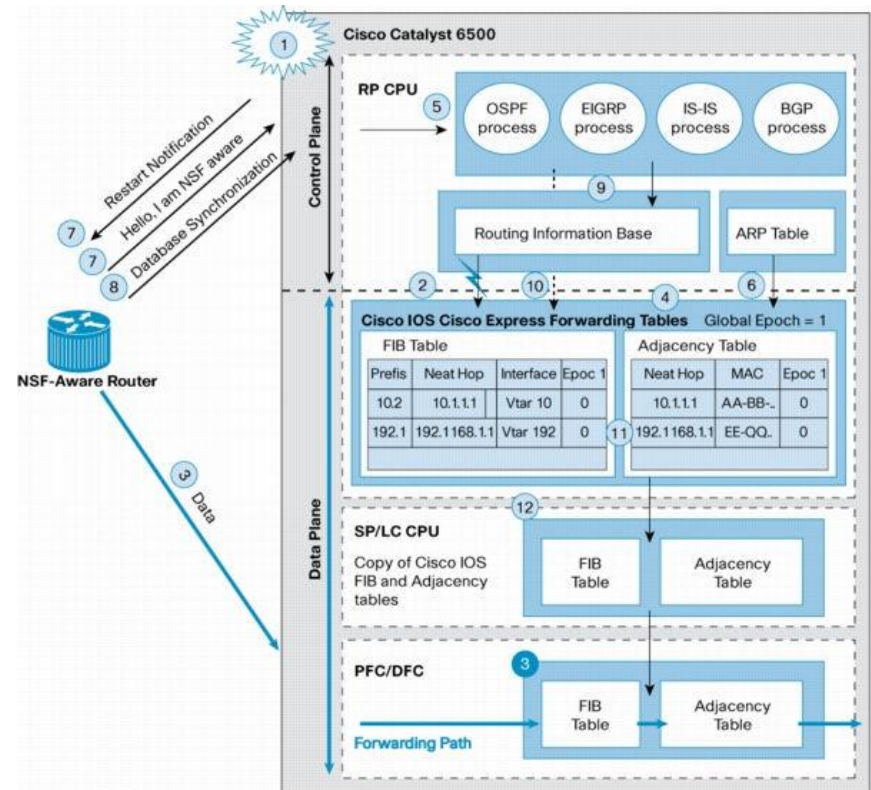

# Cisco NSF with SSO

- Supervisor redundancy mechanism in Cisco IOS enabling supervisor switchover at L2-L3-L4.
- SSO enables standby RP to take control after fault on active RP.
- Cisco NSF is L3 function that works with SSO to minimize time network unavailable following switchover, continuing to forward IP packets following RP switchover.

# Routing Protocols and NSF

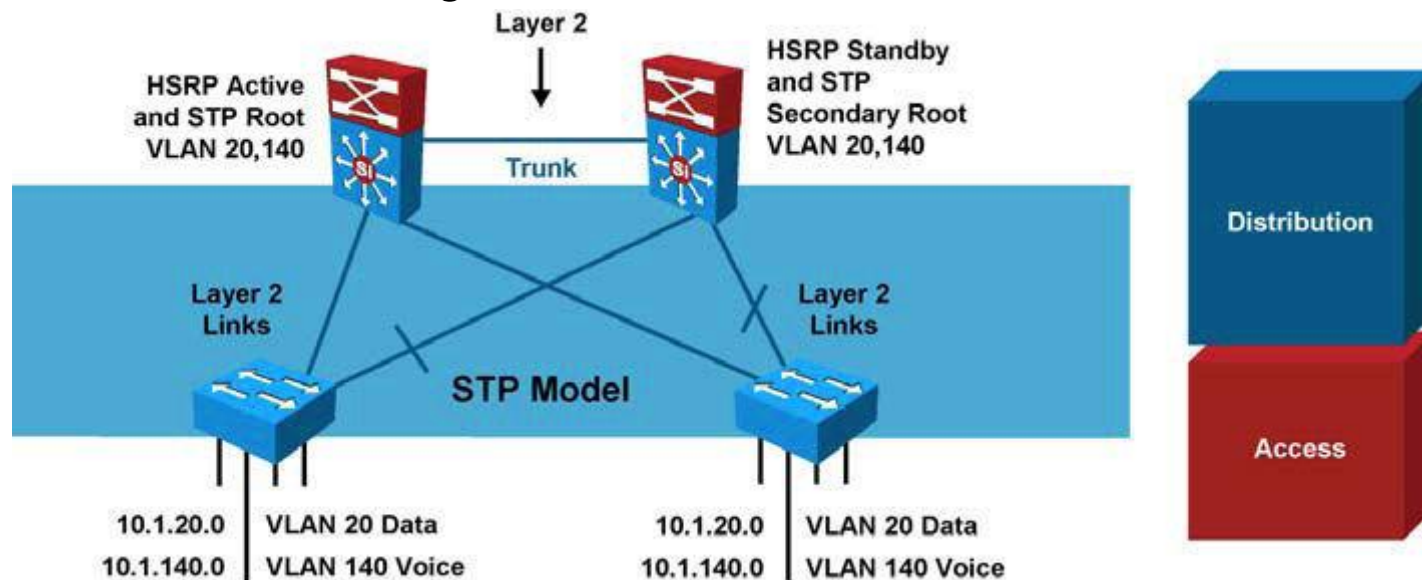

- NSF enables continued forwarding of packets along known routes while routing protocol information is being restored during switchover.
- Switchover must complete before NSF dead and hold timers expire or routing peers will reset adjacencies and reroute traffic.

# Implementing High Availability

# Distributed VLANs on Access Switches

- Use Rapid STP (RSTP) as the version of STP.
- Provide a Layer 2 trunk between the two distribution switches to avoid unexpected traffic paths and multiple convergence events.
- Place the Hot Standby Router Protocol (HSRP) primary and the STP primary root on the same distribution layer switch if you choose to load balance VLANs across uplinks.
- The HSRP and RSTP root should be colocated on the same distribution switches to avoid using the interdistribution link for transit.

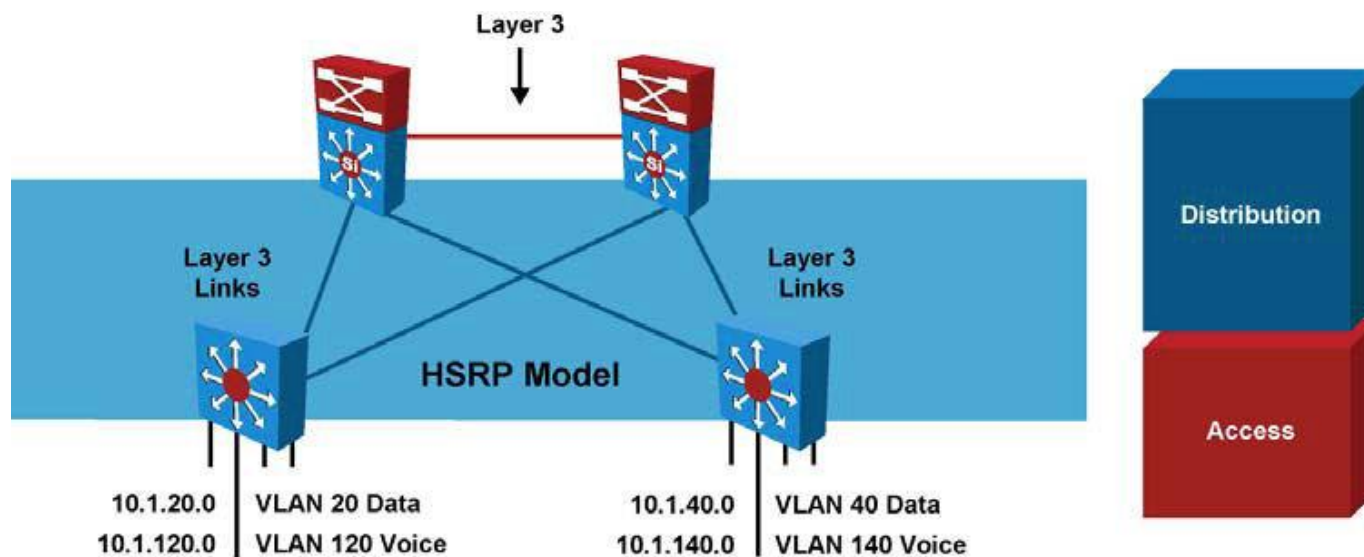

# Local VLANs on Access Switches

- No VLANs span between access layer switches across distribution switches.
- Here a single voice VLAN and a single data VLAN are restricted to a single access switch.
- Root for each VLAN aligned with active HSRP instance.
- Distribution-to-distribution L3 link required for route summarization in this design.

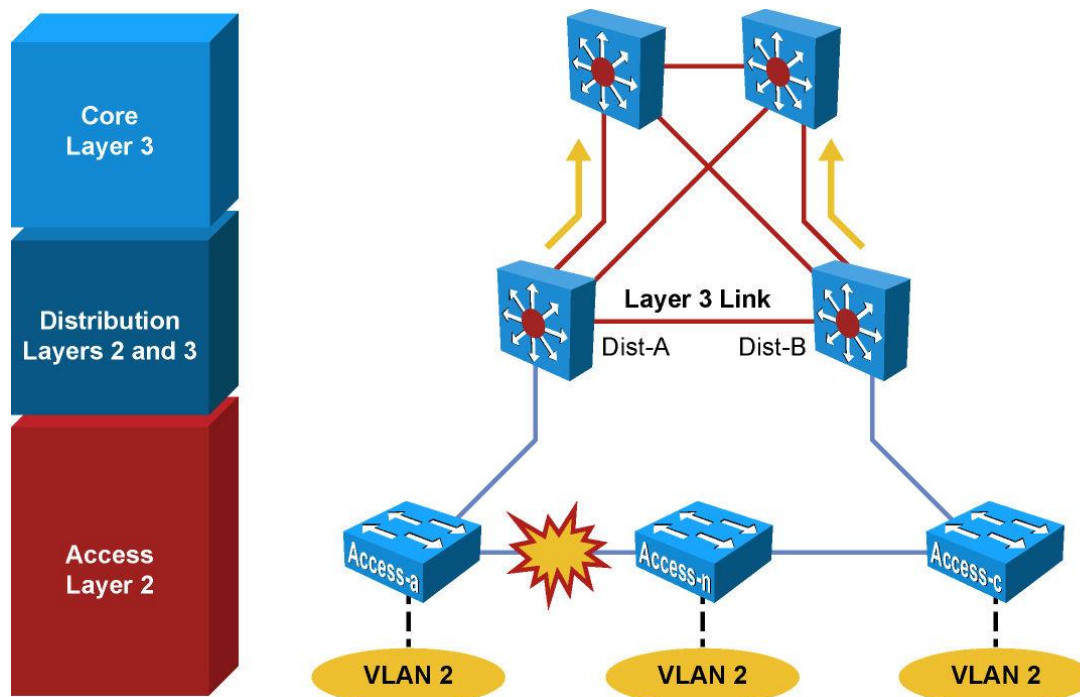

# Layer 3 Access to the Distribution Interconnection

- L3 or routed links connect distribution and access layer switches in this design – in the future this will be the standard (even the links to the end stations will be L3 in the future as prices of RPs continue to decline).
- Recommended practice is to map the L2 VLAN number to the L3 subnet for ease of use and management.

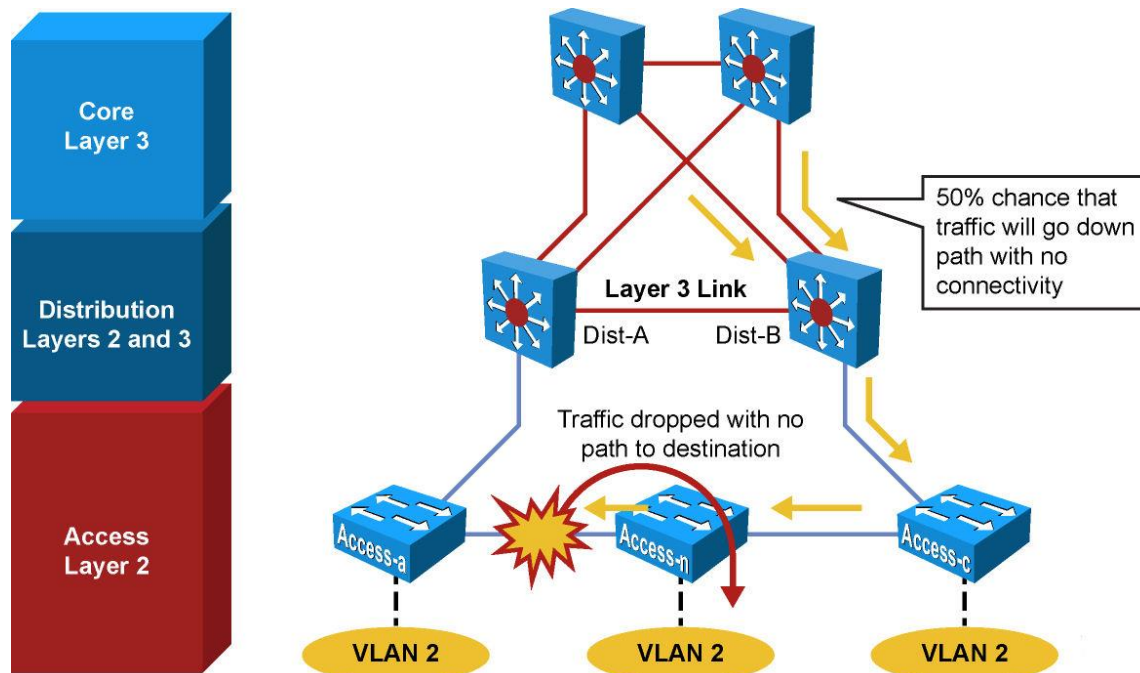

# Daisy Chaining Access Layer Switches (1)

- No links block from an STP perspective.
- Both uplinks are available to send and receive traffic.
- If a link or node in the middle of the chain or stack fails, standby HSRP peer (Dist-B) can go active as it loses connectivity to its primary peer (Dist-A).

# Daisy Chaining Access Layer Switches (2)

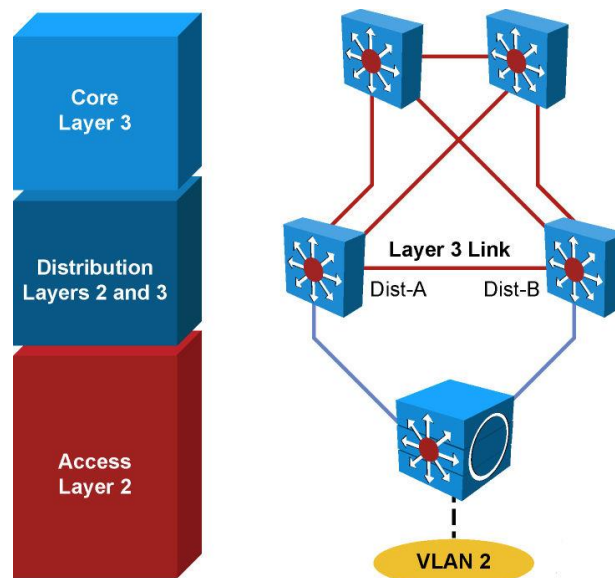

- Here the core switch sees both distribution switches advertise the VLAN 2 subnet, doing equal cost load balancing for traffic destined to VLAN 2 between Dist-A and Dist-B.
- 50% chance that return traffic arrives on distribution switch that does not have connectivity to half of stack where traffic destined. Solution: add A-a to A-c connection.

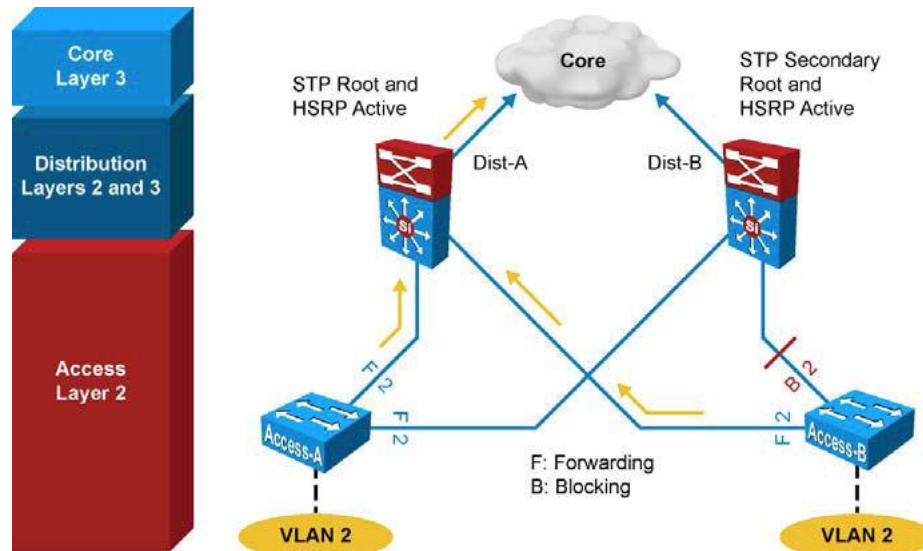

# StackWise Access Switches

- Supports recommended practice of using L3 connection between distribution switches without having to use loopback cable or perform extra configuration.
- Uses Cisco Catalyst 3750 switches in the access layer.
- Much less complex than chains or stacks of other models.
- Appears as one node from network topology perspective.

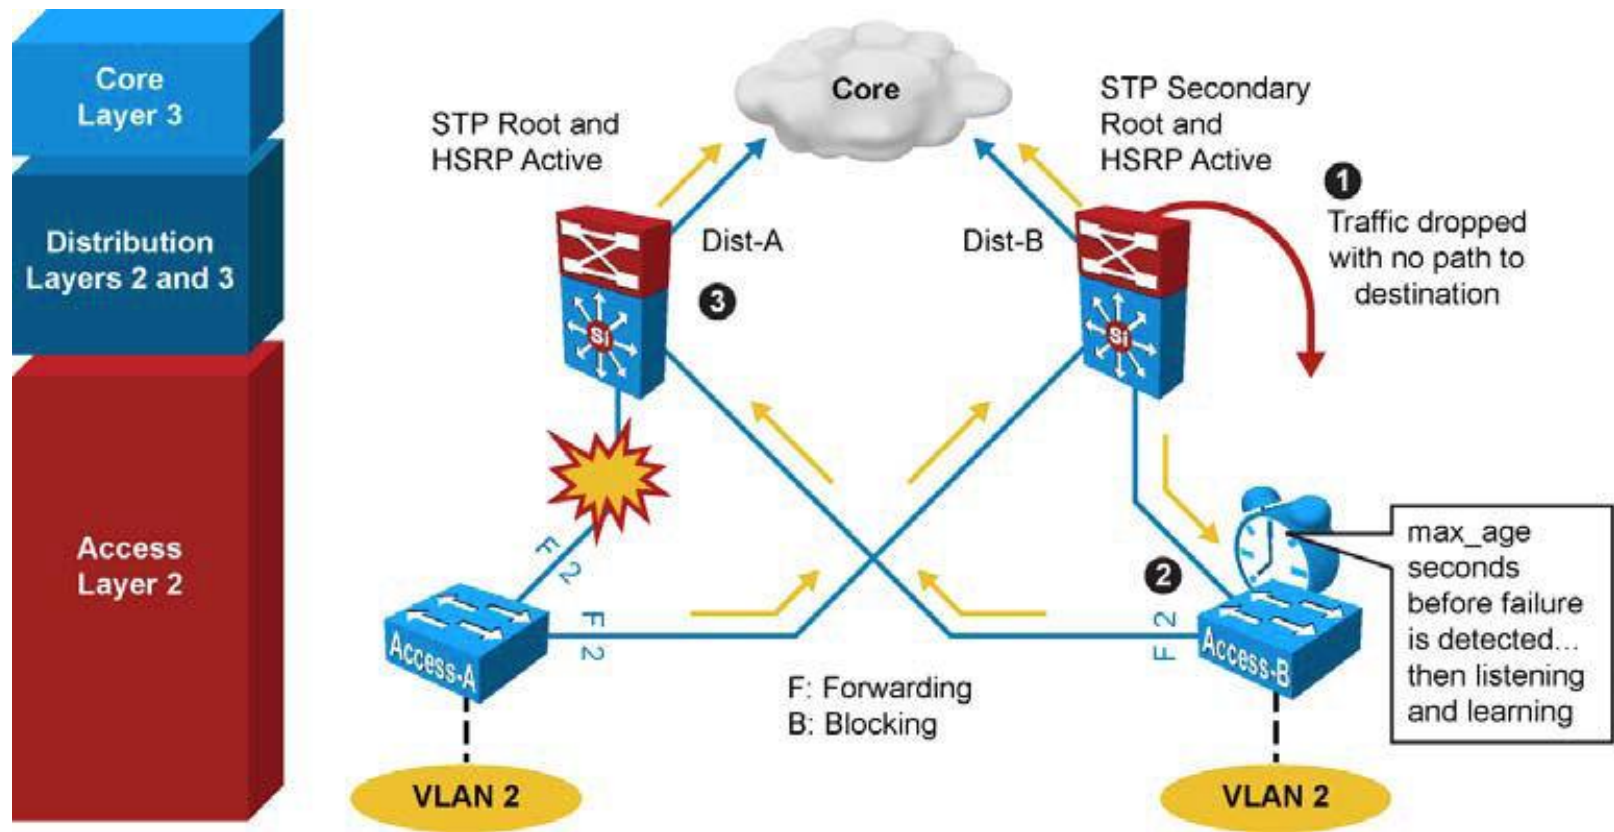

# Too Little Redundancy (1)

- VLANs span multiple access layer switches.
- No L2 link between distribution switches.
- Design is looped in figure-8 topology.
- Once access layer uplink is blocking
- HSRP hellos exchanged by transiting access switches.

# Too Little Redundancy (2)

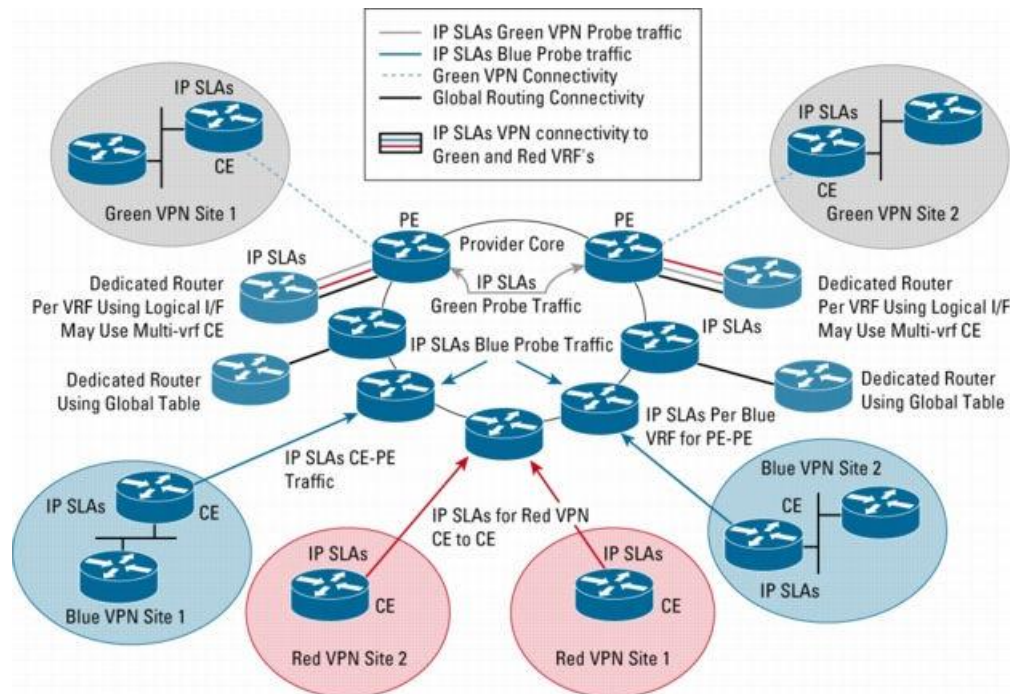

- When uplink from Access A to Distribution A fails, there are 3 convergence events.

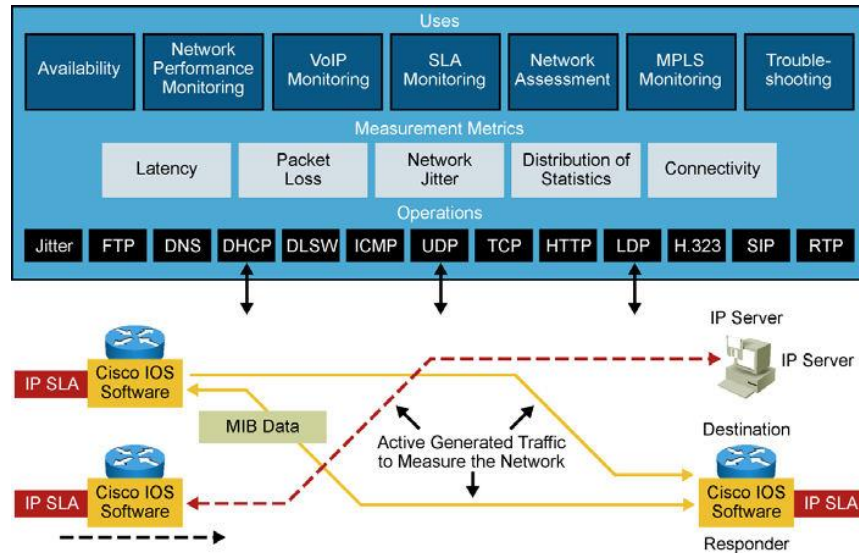

# Implementing IP Service Level Agreement

# IP Service Level Agreement

- Contract between service provider and customers.
- Specifies connectivity and performance agreements.
- Includes guaranteed level of network availability, network performance in terms of round-trip time, and network response in terms of latency, jitter, and packet loss.

# IP SLA Measurements

- In Cisco IOS, IP SLA measurement enables configuration of router to send synthetic traffic to host or router configured to respond.
- One-way travel times and packet loss are gathered.

# IP SLA Operations

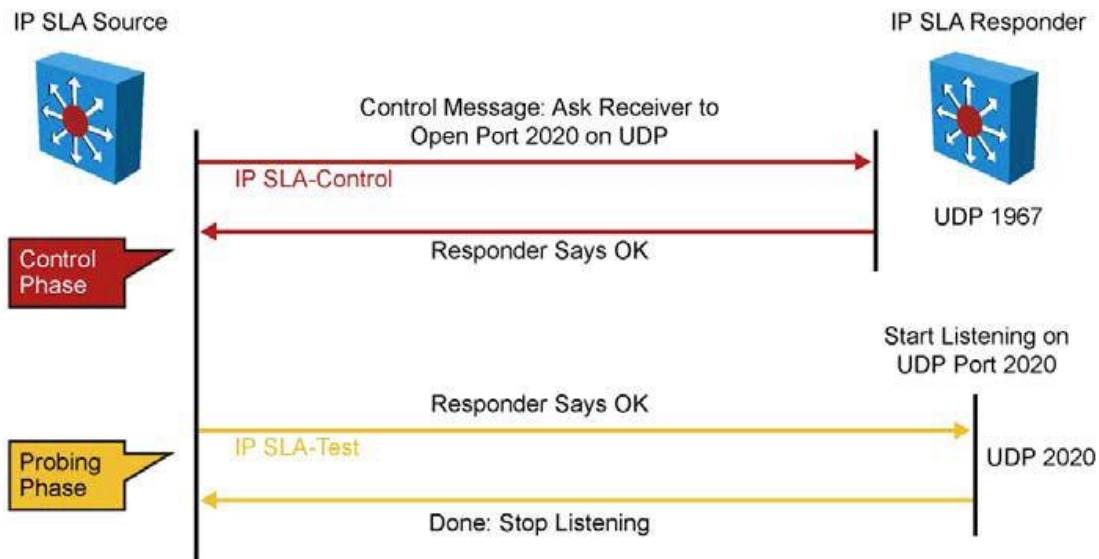

- Network engineer configures a target device, protocol, and UDP or TCP port number on the IP SLA source for each operation. Source uses IP SLA control protocol to communicate with responder before sending test packets.
- To increase security on IP SLA measurements control messages, responder can utilize MD5 authentication for securing the control protocol exchange.
- When operation finished and response received, results are stored in IP SLA MIB on source and retrieved using SNMP.
- IP SLA operations are defined by target devices. If operation is something such as DNS or HTTP, target device might be any suitable computer. For operations such as testing the port used by a database, organization might not want to risk unexpected effects and would use IP SLA responder functionality to have a router respond in place of the actual database server. Responder functionality can be enabled in a router with one command and requires no complex or per-operation configuration.

# IP SLA Source and Responder

- IP SLA source is where all IP SLA measurement probe operations are configured either by CLI or through an SNMP tool that supports IP SLA operation. Source is also the Cisco IOS device that sends probe packets. Destination of probe might be another Cisco router or another network target, such as a web server or IP host.
- Although destination of probe can be any IP device, measurement accuracy is improved with IP SLA responder. IP SLA responder is device running Cisco IOS and is configured as IP SLA measurement responder with the **ip sla monitor responder** configuration command.

# IP SLA Operation with Responder

- Network manager configures IP SLA operation by defining a target device, protocol, and port number on IP SLA source. Network manager can also configure reaction conditions. Operation is scheduled to be run for a period of time to gather statistics.

# IP SLA Responder Timestamps

- IP SLA responder timestamps are used in round-trip calculations.
- IP SLA source sends test packet at time T1.
- IP SLA responder includes receipt time (T2) and transmitted time (T3).

# Configuring IP SLA

- Step 1. Configure IP SLA probe.
  - Step 2. Activate probe.
  - Step 3. Configure tracking object.
  - Step 4. Configure action on tracking object.
- 
- The first step is to use the command `ip sla monitor` followed by a number to enter in IP SLA configuration mode.
  - The number identifies the SLA test.

# Configuring IP SLA Example

- The IP SLA test is done by sending an `ipIcmpEcho` message to the IP address 10.1.1.1 from the local interface Fa0/1 every 10 seconds.

```
SwitchB(config)# ip sla monitor 11
SwitchB(config-sla)# type echo protocol ipIcmpEcho 10.1.1.1 source-
int fa0/1
SwitchB(config-sla)# frequency 10
SwitchB(config-sla)# exit
SwitchB(config)# ip sla monitor schedule 11 life forever start-time
now
SwitchB(config)# track 1 ip sla 11 reachability
```

# Verifying IP SLA Configuration (1)

- When IP SLA is configured, the test is conducted as per the scheduled configuration. The test might succeed or fail. If you do not monitor the test results, it might fail silently.
- To display information about the test, use the `show ip sla statistics` command.

```
Switch# show ip sla statistics
Round Trip Time (RTT) for Index 1
Latest RTT: NoConnection/Busy/Timeout
Latest operation start time: 11:11:22.533 eastern Thu Jul 9 2010
Latest operation return code: Timeout
Over thresholds occurred: FALSE
Number of successes: 177
Number of failures: 6
Operation time to live: Forever
Operational state of entry: Active
Last time this entry was reset: Never
```

# Verifying IP SLA Configuration (2)

- To get more information about a given IP SLA test configuration, use the **show ip sla configuration** command. The example below shows a user displaying IP SLA configuration.

```
Switch# show ip sla configuration
IP SLAs, Infrastructure Engine-II
Entry number: 1
Owner:
Tag:
Type of operation to perform: echo
Target address/Source address: 10.1.3.10/10.1.253.1
Type Of Service parameter: 0x0
Request size (ARR data portion): 28
Operation timeout (milliseconds): 5000
Verify data: No
Vrf Name:
Schedule:
    Operation frequency (seconds): 5
    Next Scheduled Start Time: Start Time already passed
    Group Scheduled : FALSE
    Randomly Scheduled : FALSE
    Life (seconds): Forever
    Entry Ageout (seconds): never
    Recurring (Starting Everyday): FALSE
    Status of entry (SNMP RowStatus): Active
Threshold (milliseconds): 5000
<output omitted>
```

# Implementing Redundant Supervisor Engines in Catalyst Switches

# Redundancy Features on Catalyst 4500/6500

- RPR (Route Processor Redundancy) and RPR+ (only on Catalyst 6500)
- SSO (Stateful SwitchOver)
- NSF (Non-Stop Forwarding) with SSO

# Route Processor Redundancy (RPR)

- With RPR, any of the following events triggers a switchover from the active to the standby Supervisor Engine:
  - Route Processor (RP) or Switch Processor (SP) crash on the active Supervisor Engine.
  - A manual switchover from the CLI.
  - Removal of the active Supervisor Engine.
  - Clock synchronization failure between Supervisor Engines.
- In a switchover, the redundant Supervisor Engine becomes fully operational and the following events occur on the remaining modules during an RPR failover:
  - All switching modules are power-cycled.
  - Remaining subsystems on the MSFC (including Layer 2 and Layer 3 protocols) are initialized on the prior standby, now active, Supervisor Engine.
  - ACLs based on the new active Supervisor Engine are reprogrammed into the Supervisor Engine hardware.

# Route Processor Redundancy Plus (RPR+)

RPR+ enhances Supervisor redundancy compared to RPR by providing the following additional benefits:

- **Reduced switchover time:** Depending on the configuration, the switchover time is in the range of 30 seconds to 60 seconds.
- **No reloading of installed modules:** Because both the startup configuration and the running configuration stay continually synchronized from the active to the redundant Supervisor Engine during a switchover, no reloading of line modules occurs.
- **Synchronization of Online Insertion and Removal (OIR) events between the active and standby:** This occurs such that modules in the online state remain online and modules in the down state remain in the down state after a switchover.

# RPR and RPR+ Failover Time Intervals

Redundancy	Catalyst 6500 Failover Time	Catalyst 4500 Failover Time
RPR	2-4 minutes	Less than 60 seconds
RPR+	30-60 seconds	---

# Configuring and Verifying RPR+ Redundancy

- Step 1. Use the **redundancy** command to start configuring redundancy modes:
- Step 2. Use the **mode rpr-plus** command under redundancy configuration submode to configure RPR+:

```

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode rpr-plus
Switch(config-red)# end
Switch# show redundancy states
    my state = 13 -ACTIVE
peer state = 1 -DISABLED
Mode = Simplex
Unit = Primary
Unit ID = 1
Redundancy Mode (Operational) = Route Processor Redundancy Plus
Redundancy Mode (Configured) = Route Processor Redundancy Plus
Split Mode = Disabled
Manual Swact = Disabled Reason: Simplex mode
Communications = Down Reason: Simplex mode

<output omitted>

```

# Stateful Switchover (SSO)

- Provides minimal Layer 2 traffic disruption during Supervisor switchover.
- Redundant Supervisor starts up in fully initialized state and synchronizes with startup configuration and running configuration of active Supervisor.
- Standby Supervisor in SSO mode keeps in sync with active Supervisor for all changes in hardware and software states for features supported via SSO.

# Protocols and Features Supported by SSO

- 802.3x (Flow Control)
- 802.3ad (LACP) and PAgP
- 802.1X (Authentication) and Port security
- 802.3af (Inline power)
- VTP
- Dynamic ARP Inspection/DHCP snooping/IP source guard
- IGMP snooping (versions 1 and 2)
- DTP (802.1Q and ISL)
- MST/PVST+/Rapid-PVST
- PortFast/UplinkFast/BackboneFast /BPDU Guard and filtering
- Voice VLAN
- Unicast MAC filtering
- ACL (VLAN ACLs, Port ACLs, Router ACLs)
- QOS (DBL)
- Multicast storm control/broadcast storm control

# Configuring and Verifying SSO

- Step 1. Enter the **redundancy** command to start configuring redundancy modes.ancy
- Step 2. Use the **mode sso** command under redundancy configuration submode to configure RPR+:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode sso
Changing to sso mode will reset the standby. Do you want to continue?
[confirm]
Switch(config-red)# end
Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 2
Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
    Split Mode = Disabled
    Manual Swact = Enabled
Communications = Up
<output omitted>
```

# NSF with SSO

- Catalyst 4500 and 6500.
- Minimizes time that L3 network is unavailable following Supervisor switchover by continuing to forward IP packets using CEF entries built from the old active Supervisor.
- Zero or near zero packet loss.
- Supports BGP, EIGRP, OSPF, and IS-IS.
- Routing protocol neighbor relationships are maintained during Supervisor failover.
- Prevents route flapping.

# Configuring and Verifying NSF with SSO (1)

- NSF is an additional configuration option for configuring SSO. To configure NSF for OSPF, EIGRP, and IS-IS, use the `nsf router-level` command. To configure BGP for NSF support, use the `bgp gracefulrestart router-level` command.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# router bgp 100
Switch(config-router)# bgp graceful-restart
Switch(config-router)# exit
Switch(config)#router ospf 200
Switch(config-router)# nsf
Switch(config-router)# end
Switch# show ip bgp neighbors 192.168.200.1
BGP neighbor is 192.168.200.1, remote AS 200, external link
BGP version 4, remote router ID 192.168.200.1
BGP state = Established, up for 00:01:23
Last read 00:00:17, hold time is 180, keepalive interval is 60 seconds
Neighbor capabilities:
  Route refresh:advertised and received(new)
  Address family IPv4 Unicast:advertised and received
  Address family IPv4 Multicast:advertised and received
  Graceful Restart Capability:advertised and received
    Remote Restart timer is 120 seconds
  Address families preserved by peer:
    IPv4 Unicast, IPv4 Multicast
Received 1539 messages, 0 notifications, 0 in queue
Sent 100 messages, 0 notifications, 0 in queue
Default minimum time between advertisement runs is 30 seconds
```

# Configuring and Verifying NSF with SSO (2)

```

Switch# show ip ospf
Routing Process "ospf 200" with ID 192.168.20.1 and Domain ID 0.0.0.1
Supports only single TOS(TOS0) routes
Supports opaque LSA
SPF schedule delay 5 secs, Hold time between two SPF's 10 secs
Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
Number of external LSA 0. Checksum Sum 0x0
Number of opaque AS LSA 0. Checksum Sum 0x0
Number of DCbitless external and opaque AS LSA 0
Number of DoNotAge external and opaque AS LSA 0
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
External flood list length 0
Non-Stop Forwarding enabled, last NSF restart 00:02:36 ago (took 34 secs)
Area BACKBONE(0)
Number of interfaces in this area is 1 (0 loopback)
  Area has no authentication
SPF algorithm executed 3 times

```

# Understanding First Hop Redundancy Protocols

# Introduction to First Hop Redundancy

## FIRST HOP REDUNDANCY

Protocols	Attributes		
<b>Hot Standby Router Protocol (HSRP)</b> Provides default gateway redundancy using one active and one standby router; standardized but licensed by Cisco Systems	<b>HSRP</b>	<b>VRRP</b>	<b>GLBP</b>
<b>Virtual Router Redundancy Protocol (VRRP)</b> An open-standard alternative to Cisco's HSRP, providing the same functionality	<b>Standard</b>	RFC 2281	RFC 3768
<b>Gateway Load Balancing Protocol (GLBP)</b> Supports arbitrary load balancing in addition to redundancy across gateways; Cisco proprietary	<b>Load Balancing</b>	No	No
	<b>IPv6 Support</b>	Yes	No
	<b>Transport</b>	UDP/1985	IP/112
	<b>Default Priority</b>	100	100
	<b>Default Hello</b>	3 sec	1 sec
	<b>Multicast Group</b>	224.0.0.2	224.0.0.18
			224.0.0.102

**HSRP**

**VRRP**

**GLBP**

**HSRP Configuration**

```

interface FastEthernet0/0
ip address 10.0.1.2 255.255.255.0
standby version {1 | 2}
standby 1 ip 10.0.1.1
standby 1 timers <hello> <dead>
standby 1 priority <priority>
standby 1 preempt
standby 1 authentication md5 key-string <password>
standby 1 track interfaces <interfaces>
                    
```

**HSRP/GLBP Interface States**

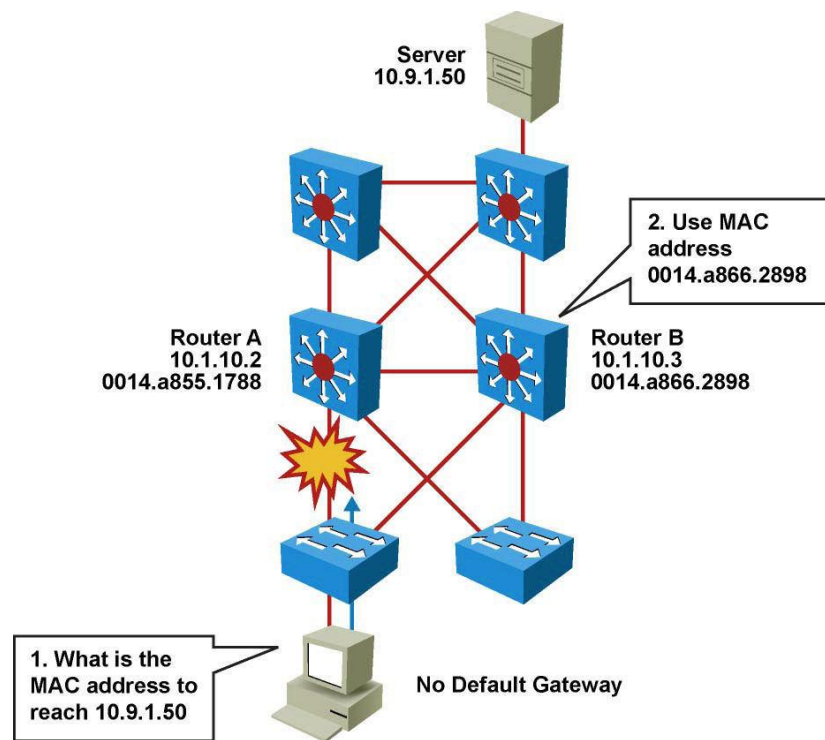

- Speak** - Gateway election in progress
- Active** - Active router/VG
- Standby** - Backup router/VG
- Listen** - Not the active router/VG

**VRRP Interface States**

- Proxy ARP
- Static Default Gateway
- HSRP
- VRRP
- GLBP

# Proxy ARP

- Legacy solution.
- Enabled by default.
- Used before default gateways were supported on IP clients.
- End station acts as if destination were on same network segment.
- Relatively slow due to reliance on aging out of ARP cache.

# Static Default Gateway

- Not dynamic.
- Does not provide secondary path.

# Hot Standby Router Protocol (HSRP)

- Cisco-proprietary gateway redundancy protocol.
- Participating routers talk to each other and agree on a virtual router with a virtual IP address which end systems use as a default gateway.

# HSRP Failover

- When active router or links between routers fail, the standby router stops seeing hello messages from active router. Standby router then assumes role of forwarding router.
- Because new forwarding router assumes both IP and MAC address of virtual router, end stations see no disruption in service.

# HSRP Operation

- HSRP active and standby routers send hello messages to multicast address 224.0.0.2 UDP port 1985.
- Hello messages used to communicate between routers within HSRP group.
- All routers in HSRP group need to be L2-adjacent.
- All routers in an HSRP group have specific roles and interact in specific ways:
  - **Virtual router**
  - **Active router**
  - **Standby router**
  - **Other routers**

# HSRP MAC Address

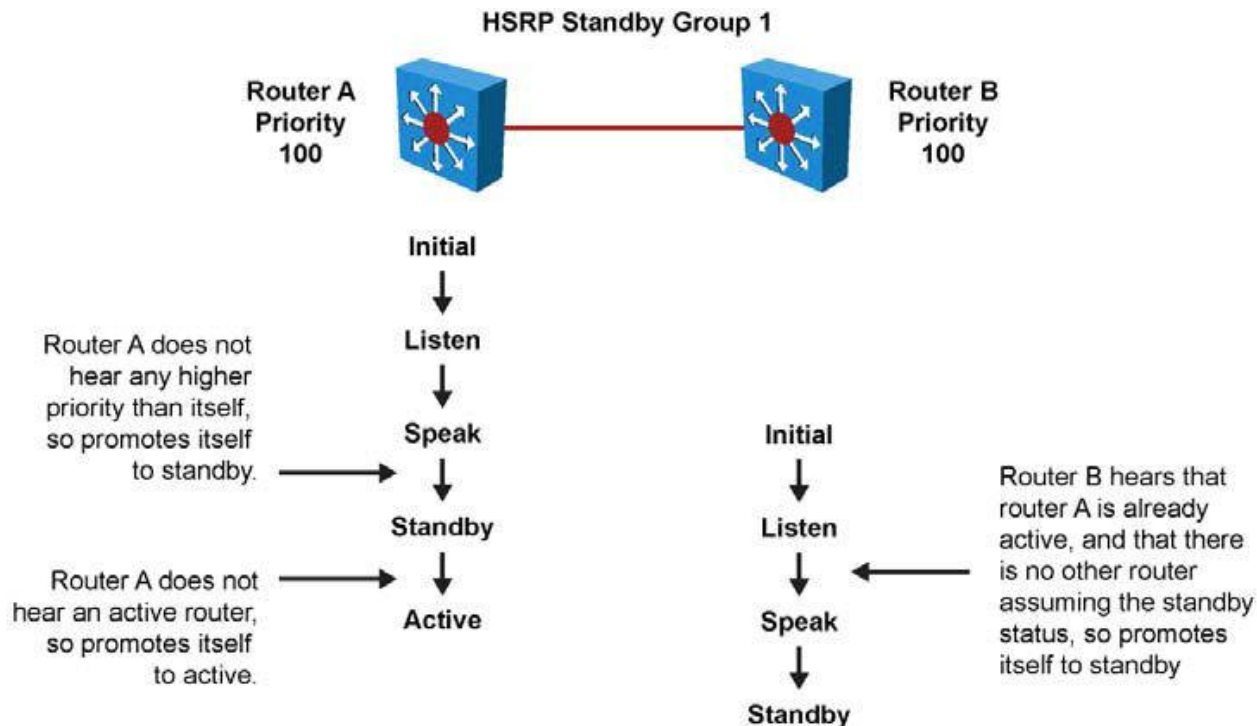

- Router A assumes the active role and forwards all frames addressed to the assigned HSRP MAC address of **0000.0c07.acxx**, where xx is the HSRP group identifier.

# HSRP States

State	Definition
Initial	The beginning state. The initial state indicates that HSRP does not run. This state is entered via a configuration change or when an interface first comes up.
Listen	The router knows the virtual IP address, but the router is neither the active router nor the standby router. It listens for hello messages from those routers.
Speak	The router sends periodic hello messages and actively participates in the election of the active or standby router. A router cannot enter speak state unless the router has the virtual IP address.
Standby	The router is a candidate to become the next active router and sends periodic hello messages. With the exclusion of transient conditions, there is, at most, one router in the group in standby state.
Active	The router currently forwards packets that are sent to the group virtual MAC address. The router sends periodic hello messages. With the exclusion of transient conditions, there must be, at the most, one router in the active state in the group.

# HSRP State Transition

- Router A starts. As it is the first router for standby Group 1 in the subnet, it transits through the listen and speak states and then becomes the active router.
- Router B starts after Router A. While Router B is in listen state, Router A is already assuming the standby and then the active role. As there is already an existing active router, Router B assumes the standby role.

# HSRP Active Router and Spanning Tree Topology

- In a redundant spanning-tree topology, some links are blocked. The spanning-tree topology has no awareness about the HSRP configuration. There is no automatic relationship between the HSRP active router election process and the Spanning Tree Root Bridge election.
- When configuring both spanning tree and HSRP (or any other first hop redundancy protocol), you must make sure that the active router is the same as the root bridge for the corresponding VLAN. When the root bridge is different from the HSRP active router, a suboptimal path can result, as illustrated.

# Configuring HSRP

- Configure HSRP on the interface.

```
Switch(config-if) #
```

```
standby group-number ip ip-address
```

- The group number is optional and indicates the HSRP group to which this interface belongs.
- Specifying a unique group number in the standby commands enables the creation of multiple HSRP groups. The default group is 0.
- The IP address is that of the virtual router IP address for the HSRP group.

# Configuring HSRP Priority and Preempt

- To set the HSRP priority value of a router, enter this command in interface configuration mode:

```
standby group-number priority priority-value
```

- The priority value can be from 0 to 255. The default value is 100.
- During the election process, the router with the highest priority in an HSRP group becomes the active router. If a tie occurs, the router with the highest configured IP address becomes active.
- If the routers do not have **preempt** configured, a router that boots up significantly faster than the others in the standby group becomes the active router, regardless of the configured priority. The former active router can be configured to resume the forwarding router role by preempting a router with a lower priority.
- To enable a router to resume the forwarding router role, enter this command in interface configuration mode:

```
standby [group-number] preempt [delay {minimum seconds reload  
seconds sync seconds}]
```

# HSRP Configuration Example

- Routers A and B are configured with priorities of 110 and 90, respectively. The configuration of Router A is displayed.
- The **preempt** keyword ensures that Router A will be the HSRP active router as long its interface is active.

HSRP Standby Group 10

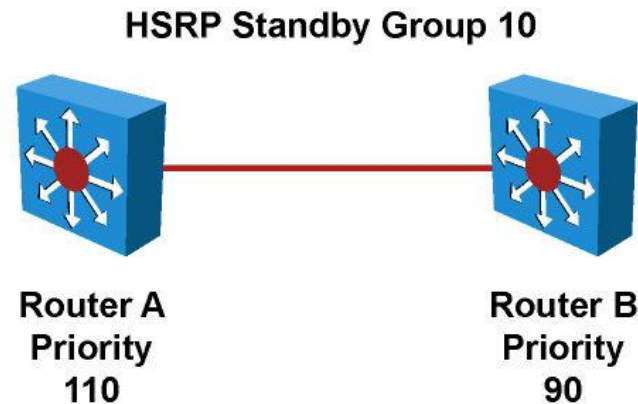

```
RouterA(config)# interface vlan 10
RouterA(config-if)# ip address 10.1.1.2 255.255.255.0
RouterA(config-if)# standby 10 ip 10.1.1.1
RouterA(config-if)# standby 10 priority 110
RouterA(config-if)# standby 10 preempt
```

# HSRP Authentication Example

- HSRP authentication prevents rogue routers on the network from joining the HSRP group. HSRP authentication is enabled by configuration of an authentication string on all member devices of the HSRP group.
- The authentication string is a maximum of 8 characters and the default keyword is **cisco**.

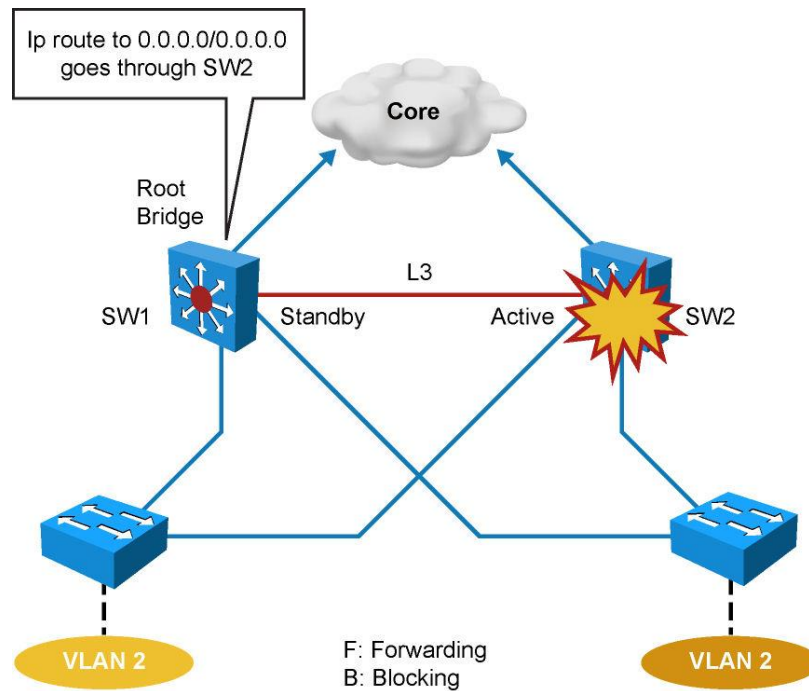

```

RouterA(config)# interface vlan 10
RouterA(config-if)# ip address 10.1.1.2 255.255.255.0
RouterA(config-if)# standby 10 ip 10.1.1.1
RouterA(config-if)# standby 10 priority 110
RouterA(config-if)# standby 10 preempt
RouterA(config-if)# standby 10 authentication xyz123
  
```

# HSRP Timer Considerations and Configuration

Variable	Description
<i>group-number</i>	(Optional) Group number on the interface to which the timers apply. The default is 0.
<i>msec</i>	(Optional) Interval in milliseconds. Millisecond timers allow for faster failover.
<i>hellotime</i>	Hello interval in seconds. This is an integer from 1 through 255. The default is 3 seconds.
<i>holdtime</i>	Time, in seconds, before the active or standby router is declared to be down. This is an integer from 1 through 255. The default is 10 seconds.

# HSRP Timers Configuration Example

```

RouterA(config)# interface vlan 10
RouterA(config-if)# ip address 10.1.1.2 255.255.255.0
RouterA(config-if)# standby 10 ip 10.1.1.1
RouterA(config-if)# standby 10 priority 110
RouterA(config-if)# standby 10 preempt
RouterA(config-if)# standby 10 authentication xyz123
RouterA(config-if)# standby 10 timers msec 200 msec 750
RouterA(config-if)# standby 10 preempt delay minimum 225
    
```

# HSRP Versions

- HSRP version 1 is the default in IOS and it enables group numbers up to 255. Because one can have up to 4095 VLANs, one has to reuse the same HSRP group number on multiple interfaces if needed. This is allowed even though it might cause some confusion.
- HSRPv1 uses the Virtual MAC address of the form 0000.0C07.ACXX (XX = HSRP group), and the HSRPv1 hello packets are sent to multicast address 224.0.0.2.
- HSRP version 2 has been added to IOS since 12.2 46SE or later and it enables group numbers up to 4095. This enables you to use the VLAN number as the group number.
- With HSRPv2, the MAC address of the virtual router and the multicast address for the hello messages has been changed. The virtual MAC address is 0000.0C9F.FXXX (XXX=HSRP group), and hello packets are sent to multicast address 224.0.0.102.
- Also, HSRPv2 has a different packet format from HSRPv1. Ensure that the same version is configured on all routers in a HSRP group. Otherwise hello messages are not understood. Version 1 is the default.
- Use the following command to change the version:

```
Switch(config-if)# standby <hsrp group number> version 2
```

# HSRP Interface Tracking (1)

- Enables priority of standby group router to be automatically adjusted based on availability of tracked interfaces.
- When tracked interface becomes unavailable, HSRP priority is decreased.
- Ensures the router with unavailable interface relinquishes active router role.

# HSRP Interface Tracking (2)

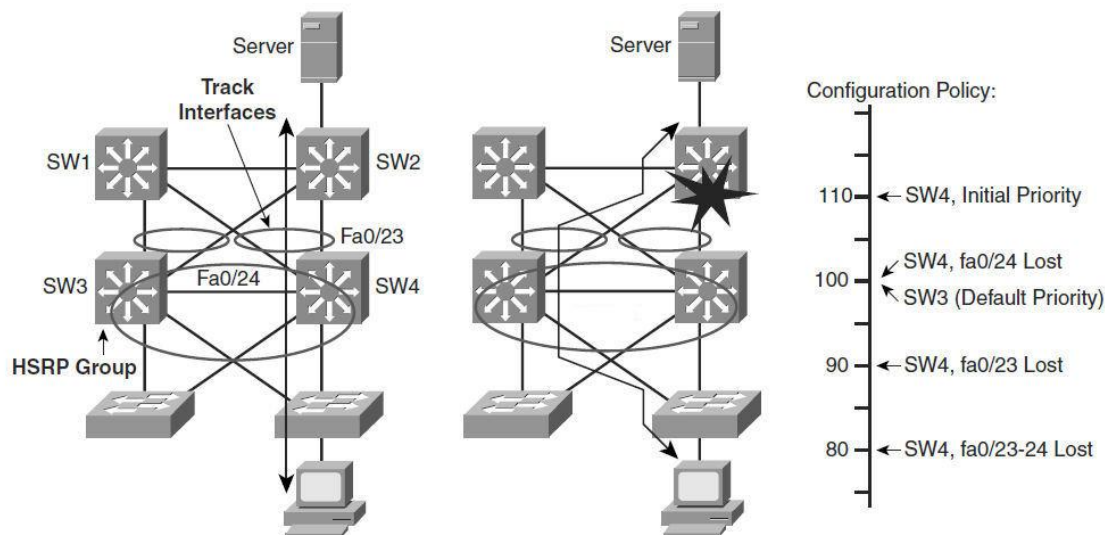

- Configure interface tracking.

```
Switch(config-if)
```

```
standby [group-number] track interface-type interface-number [interface-priority]
```

Variable	Description
<i>group-number</i>	(Optional) Indicates the group number on the interface to which the tracking applies. The default number is 0.
<i>interface-type</i>	Indicates the interface type (combined with the interface number) that will be tracked.
<i>interface-number</i>	Indicates the interface number (combined with the interface type) that will be tracked.
<i>interface-priority</i>	(Optional) Indicates the amount by which the hot standby priority for the router is decremented when the interface becomes disabled. The priority of the router is incremented by this amount when the interface becomes available. The default value is 10.

# HSRP Interface Tracking (3)

To configure HSRP with interface tracking, follow these steps:

- Step 1. Configure the standby group.
- Step 2. Configure priority (default 100).
- Step 3. Configure preempt on all devices within the HSRP group.
- Step 4. Configure the tracked interfaces and decrement (default decrement 10).

# HSRP Interface Tracking (4)

```

SW4(config)# interface vlan 10
SW4(config-if)# ip address 10.1.1.2 255.255.255.0
SW4(config-if)# standby 10 ip 10.1.1.1
SW4(config-if)# standby 10 priority 110
SW4(config-if)# standby 10 preempt
SW4(config-if)# standby 10 track fastethernet0/23 20
SW4(config-if)# standby 10 track fastethernet0/24
    
```

# HSRP Object Tracking

- The HSRP tracking feature can be used to track an object. When the conditions defined by this object are fulfilled, the router priority remains the same. As soon as the verification defined by the object fails, the router priority is decremented.
- Tracked objects are defined in global configuration with the **track** keyword, followed by an object number.
- You can track up to 500 objects.

```
Switch(config)# track 1 ?
interface      Select an interface to track
ip             IP protocol
list          Group objects in a list
rtr           Response Time Reporter (RTR) entry
```

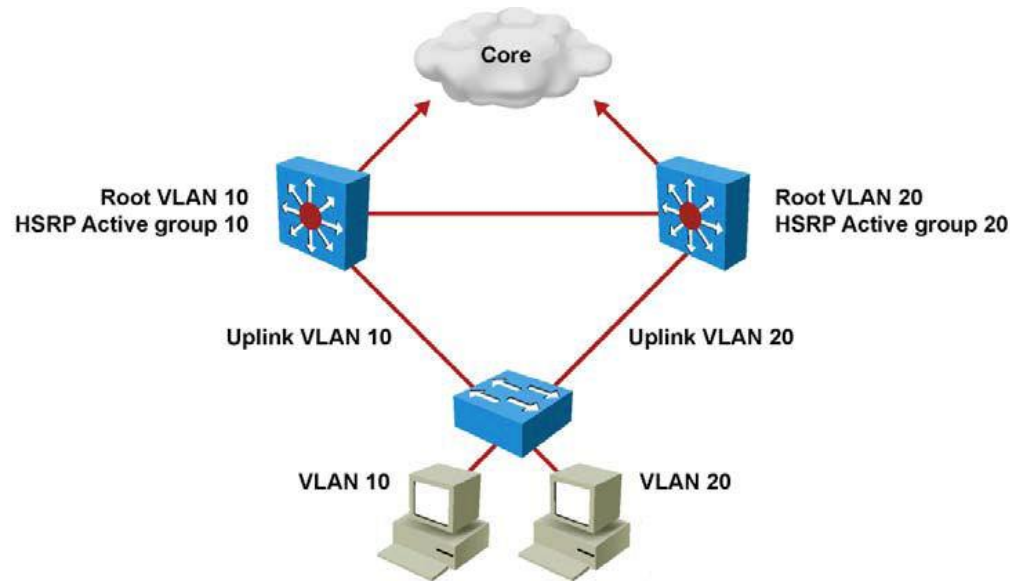

# HSRP and IP SLA Tracking

```

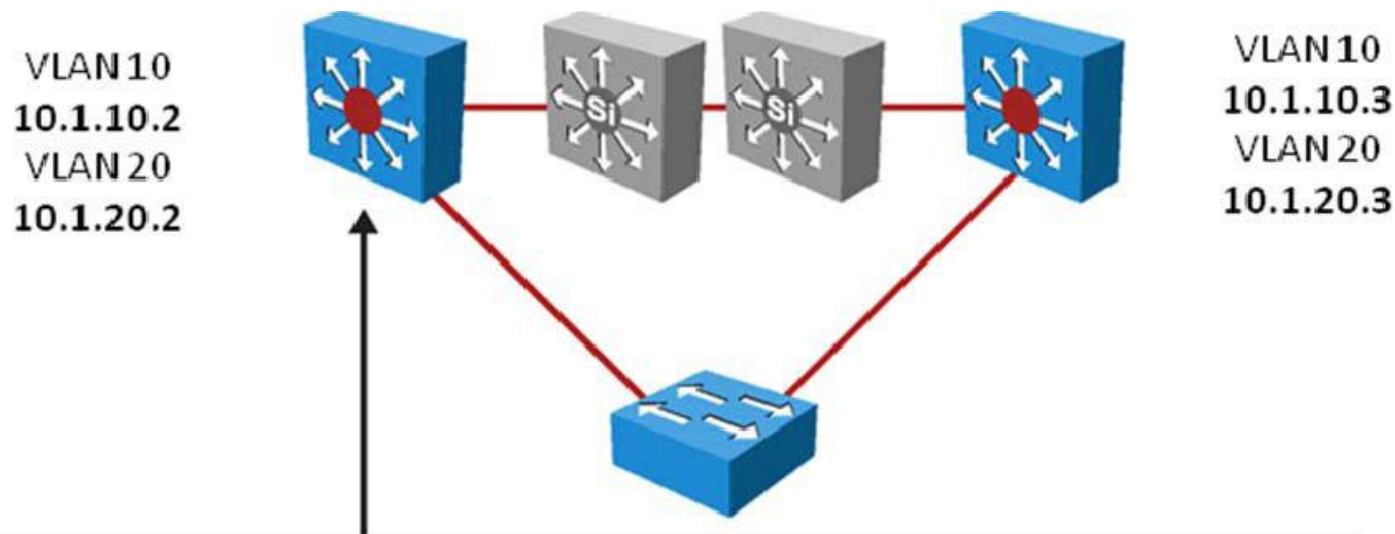

sw(config)# ip sla 18
sw(config-sla)# icmp-echo 10.9.9.1
sw(config)# ip sla schedule 18 start-time now life forever
sw(config)# track 90 rtr 18 state
sw(config)# interface vlan10
sw(config-if)# ip address 10.1.1.2 255.255.255.0
sw(config-if)# standby 10 ip 10.1.1.1
sw(config-if)# standby 10 priority 110
sw(config-if)# standby 10 preempt
sw(config-if)# standby 10 track 90 decrement 20
    
```

# Multiple HSRP Groups (1)

- HSRP allows for only one active router in the same subnet. In a typical network, engineers would want to use all available routers to load share the traffic going across the network. Multigroup HSRP enables routers to simultaneously provide redundant backup and perform load sharing across different IP subnets.
- In the figure, two HSRP-enabled routers participate in two separate VLANs, using 802.1Q. Running HSRP over trunks enables users to configure redundancy among multiple routers that are configured as front ends for VLAN IP subnets.

# Multiple HSRP Groups (2)

```

switch(config)# spanning-tree vlan 10 root primary
switch(config)# spanning-tree vlan 20 root secondary
switch(config)# interface vlan 10
switch(config-if)# ip address 10.1.10.2 255.255.255.0
switch(config-if)# standby 10 ip 10.1.10.1
switch(config-if)# standby 10 priority 110
switch(config-if)# standby 10 preempt
switch(config)# interface vlan 20
switch(config-if)# ip address 10.1.20.2 255.255.255.0
switch(config-if)# standby 20 ip 10.1.20.1
switch(config-if)# standby 20 priority 90
switch(config-if)# standby 20 preempt
    
```

# HSRP Monitoring (1)

- Use the **show standby** family of commands to verify HSRP state. Several arguments can be used.
- The **show standby brief** command displays a summary of the HSRP configurations.
- For each standby group, you can verify the local router neighbors.

```
Switch# show standby brief
                P indicates configured to preempt.
                |
Interface Grp  Pri  P State  Active      Standby      Virtual IP
Vl10        10   120  P Active local      10.1.10.3    10.1.10.1
Vl20        20   90   P Standby 10.1.20.3   local        10.1.20.1
Switch#show standby neighbor vlan10
HSRP neighbors on Vlan10
 10.1.10.3
   Active groups: 10
   No standby groups
```

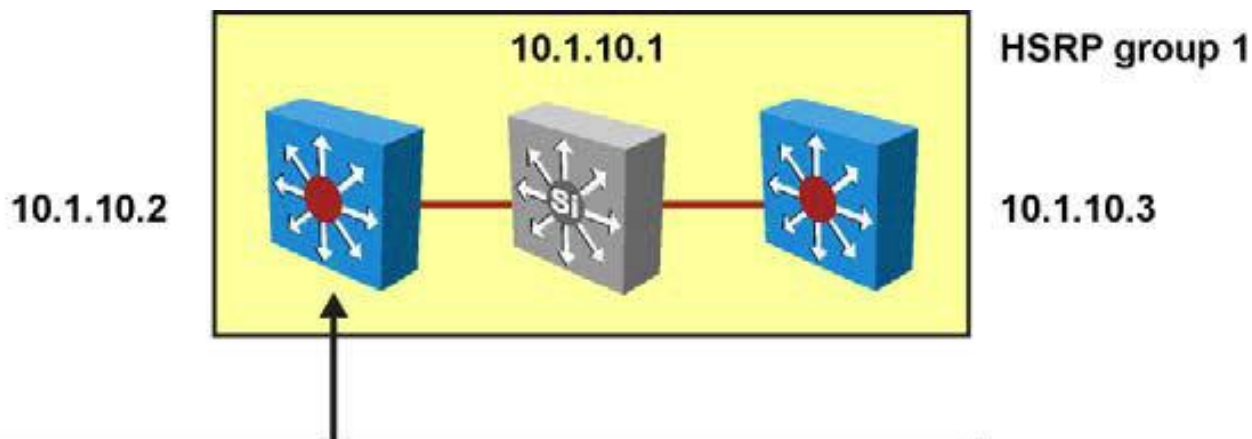

# HSRP Monitoring (2)

When simply typing **show standby**, a complete display is provided.

```
Switch# show standby
Vlan10 - Group 10
State is Active
Virtual IP address is 10.1.10.1
Active virtual MAC address is 0000.0c07.ac0a
Local virtual MAC address is 0000.0c07.ac0a (v1 default)
Hello time 3 sec, hold time 10 sec
Next hello sent in 1.248 secs
Preemption enabled
Active router is local
Standby router is 10.1.10.3, priority 90 (expires in 10.096 sec)
Priority 120 (configured 120)
Track interface Port-channel31 state Up decrement 30
Track interface Port-channel32 state Up decrement 30
Group name is "hsrp-Vl10-10" (default)
Vlan20 - Group 20
State is Standby
Virtual IP address is 10.1.20.1 Active virtual MAC address is 0000.0c07.ac14
Local virtual MAC address is 0000.0c07.ac14 (v1 default)
Hello time 3 sec, hold time 10 sec
Next hello sent in 2.064 secs
Preemption enabled
Active router is 10.1.10.3, priority 120 (expires in 10.032 sec)
Standby router is local
Priority 90 (configured 90)
Group name is "hsrp-Vl20-20" (default)
```

# HSRP Monitoring (3)

- The IP address and corresponding MAC address of the virtual router are maintained in the ARP table of each router in an HSRP group.
- The command `show ip arp` displays the ARP cache on a multilayer switch.

```

switch# show ip arp
Protocol  Address      Age (min)  Hardware Addr  Type   Interface
Internet  10.1.10.2    -          0014.a855.1788 ARPA    Vlan10
Internet  10.1.10.3    4          0014.a866.2898 ARPA    Vlan10
Internet  10.1.10.1    -          0000.0c07.ac0a ARPA    Vlan10
  
```

# HSRP Debug Commands

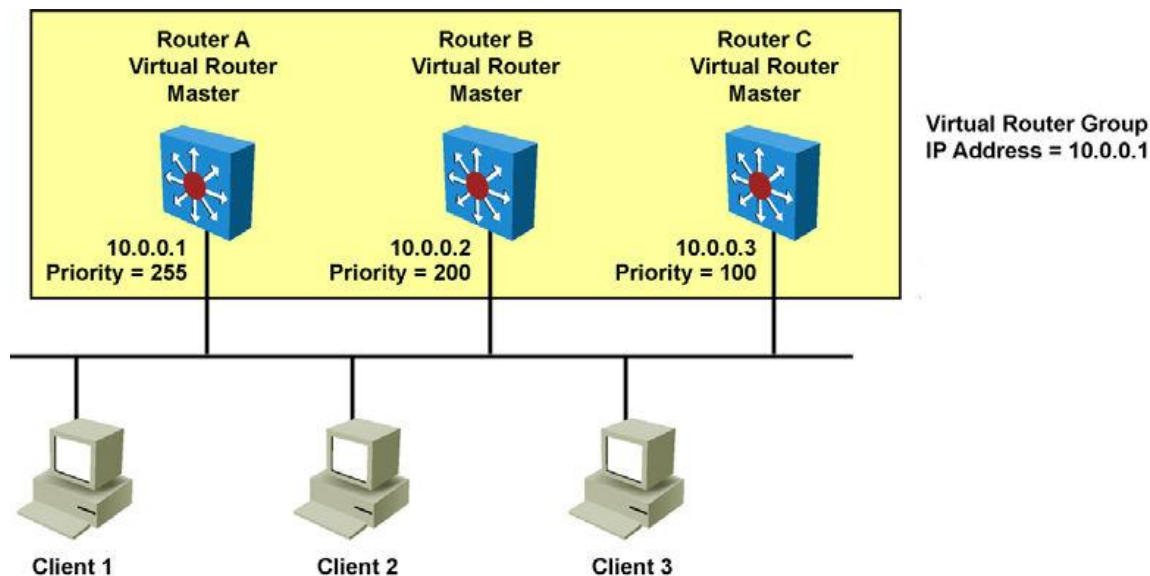

Command	Description
Switch# <b>debug standby</b> <b>[errors] [events] [packets]</b>	Displays all state changes to HSRP, including all hello packets. Arguments minimize output.
Switch# <b>debug standby terse</b>	Displays all HSRP errors, events, and packets, except hello and advertisement packets.

# Virtual Router Redundancy Protocol (VRRP)

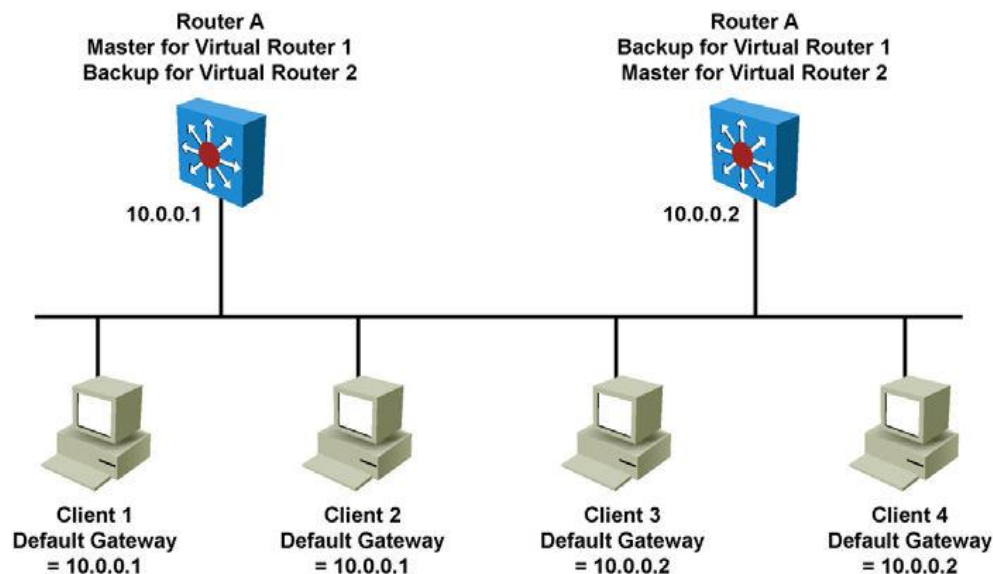

HSRP	VRRP
HSRP is a Cisco proprietary protocol, created in 1994, and formalized with the RFC 2281 in March 1998.	VRRP is an IEEE standard (RFC 2338 in 1998; then RFC 3768 in 2005) for router redundancy.
16 groups max.	255 groups max.
1 active, 1 standby, several candidates.	1 active, several backups.
Virtual IP is different from Active and Standby real IP addresses.	Virtual IP can be the same as one of the group members real IP address.
Uses 224.0.0.2 for hello packets.	Uses 224.0.0.18 for hello packets.
Default timers: hello 3 s, holdtime 10 s.	The default timers are shorter in VRRP than HSRP. This often gave VRRP the reputation of being faster than HSRP.
Can track interfaces or objects.	Can track only objects.
Uses authentication within each group by default. When authentication is not configured, a default authentication, using "cisco" as the password.	Supports plaintext and HMAC/MD5 authentication methods (RFC 2338). The new VRRP RFC (RFC 3768) removes support for these methods. The consequence is that VRRP does not support authentication anymore. Nevertheless, current Cisco IOS still supports the RFC 2338 authentications mechanisms.

# VRRP Scenario

- Routers A, B, and C are members of a VRRP group. The IP address of the virtual router is the same as that of the LAN interface of Router A (10.0.0.1). Router A is responsible for forwarding packets sent to this IP address.
- The clients have a gateway address of 10.0.0.1. Routers B and C are backup routers. If the master router fails, the backup router with the highest priority becomes the master router. When Router A recovers, it resumes the role of master router.

# VRRP Scenario (1)

- Here is a LAN topology in which VRRP is configured so that Routers A and B share the load of being the default gateway for Clients 1 through 4. Routers A and B act as backup virtual routers to one another should either one fail.
- Two virtual router groups are configured. For virtual Router 1, Router A is the owner of IP address 10.0.0.1 and is therefore the master virtual router for clients configured with that default gateway address. Router B is the backup virtual router to Router A.
- For virtual Router 2, Router B is the owner of IP address 10.0.0.2 and is the master virtual router for clients configured with the default gateway IP address 10.0.0.2. Router A is the backup virtual router to Router B.

# VRRP Scenario (2) – Transition Process

Step	Description	Notes
1.	Router A is currently the master, so it sends advertisements by default every 1 second.	Router A is the only device sending advertisements.
2.	Router A fails.	Advertisements stop.
3.	Router B and Router C stop receiving advertisements and wait for their respective master down interval to expire before transitioning to the master state.	By default, the master down interval is 3 seconds plus the skew time.
4.	Because the skew time is inversely proportional to priority, the master down interval of Router B is less than that of Router C. Router B has a master down interval of approximately 3.2 seconds. Router C has a master down interval of approximately 3.6 seconds.	The skew time for Router B equals $(256 - 200) / 256$ , which is approximately equal to 0.2 seconds. The skew time for Router C equals $(256 - 100) / 256$ , which is approximately equal to 0.6 seconds.
5.	Router B transitions to the master state after 3.2 seconds and starts sending advertisements.	---
6.	Router C receives the advertisement from the new master, so it resets its master down interval and remains in the backup state.	---

# Configuring VRRP

Step	Description
1.	<p>To enable VRRP on an interface. This makes the interface a member of the virtual group identified with the IP virtual address:</p> <pre>Switch(config-if)# <b>vrrp</b> group-number <b>ip</b> virtual-gateway-address</pre>
2.	<p>To set a VRRP priority for this router for this VRRP group: Highest value wins election as active router. Default is 100. If routers have the same VRRP priority, the gateway with the highest real IP address is elected to become the master virtual router:</p> <pre>Switch(config-if)# <b>vrrp</b> group-number <b>priority</b> priority-value</pre>
3.	<p>To change timer and indicate if it should advertise for master or just learn for backup routers:</p> <pre>Switch(config-if)# <b>vrrp</b> group-number <b>timers</b> <b>advertise</b> timer-value</pre> <pre>Switch(config-if)# <b>vrrp</b> group-number <b>timers</b> <b>learn</b></pre>

# VRRP Configuration Example (1)

```

RouterA# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
RouterA(config)# interface vlan 1
RouterA(config-if)# ip address 10.0.2.1 255.255.255.0
RouterA(config-if)# vrrp 1 ip 10.0.2.254
RouterA(config-if)# vrrp 1 timers advertise msec 500
RouterA(config-if)# end

RouterB# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
RouterB(config)# interface vlan 1
RouterB(config-if)# ip address 10.0.2.2 255.255.255.0
RouterB(config-if)# vrrp 1 ip 10.0.2.254
RouterB(config-if)# vrrp 1 priority 90
RouterB(config-if)# vrrp 1 timers learn
RouterB(config-if)# end

```

# VRRP Configuration Example (2)

```
RouterA# show vrrp interface vlan 1
```

```
Vlan1 - Group 1
```

```
State is Master
```

```
Virtual IP address is 10.0.2.254
```

```
Virtual MAC address is 0000.5e00.0101
```

```
Advertisement interval is 0.500 sec
```

```
Preemption is enabled
```

```
min delay is 0.000 sec
```

```
Priority is 100
```

```
Master Router is 10.0.2.1 (local), priority is 100
```

```
Master Advertisement interval is 0.500 sec
```

```
Master Down interval is 2.109 sec
```

# VRRP Configuration Example (3)

```
RouterB# show vrrp interface vlan 1
```

```
Vlan1 - Group 1
```

```
State is Backup
```

```
Virtual IP address is 10.0.2.254
```

```
Virtual MAC address is 0000.5e00.0101
```

```
Advertisement interval is 0.500 sec
```

```
Preemption is enabled
```

```
min delay is 0.000 sec
```

```
Priority is 90
```

```
Master Router is 10.0.2.1, priority is 100
```

```
Master Advertisement interval is 0.500 sec
```

```
Master Down interval is 2.109 sec (expires in 1.745 sec)
```

# Gateway Load Balancing Protocol (GLBP)

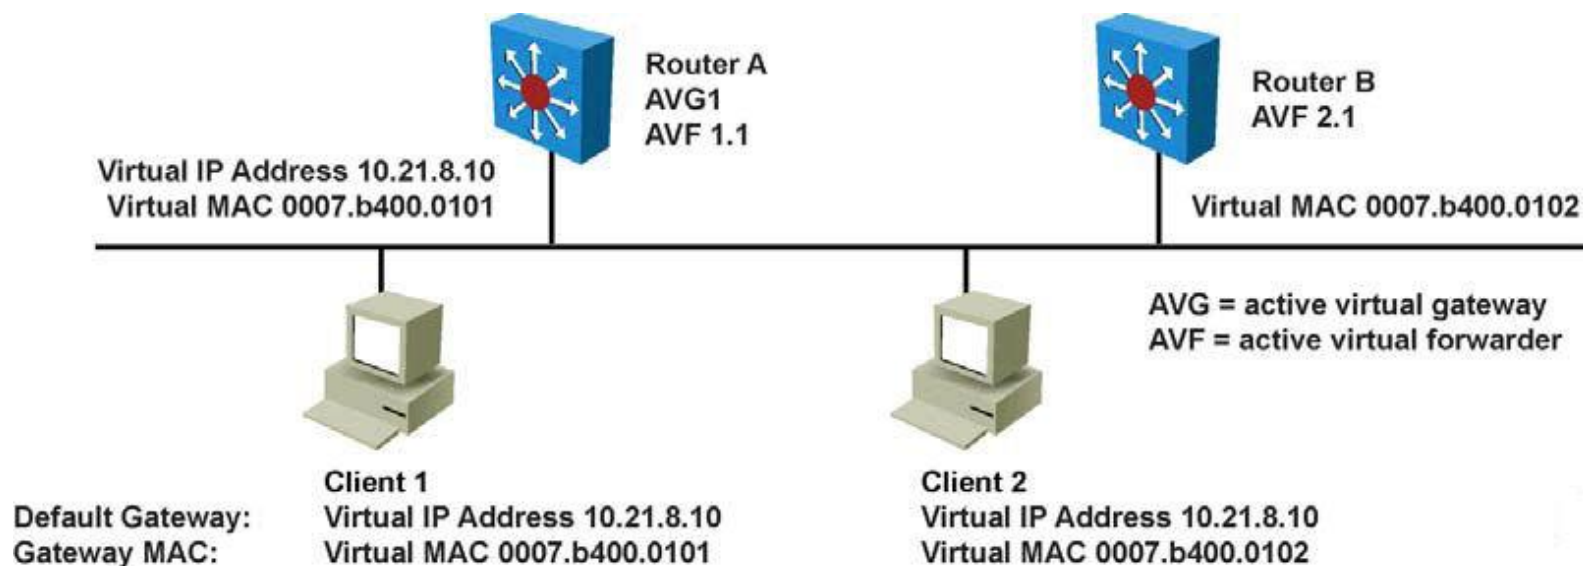

HSRP	GLBP
Cisco Proprietary, 1994	Cisco Proprietary, 2005
16 groups max.	1024 groups max.
1 active, 1 standby, several candidates.	1 AVG, several AVF, AVG load balances traffic among AVF and AVGs
Virtual IP is different from Active and Standby real IP addresses.	Virtual IP is different from AVG and AVF real IP addresses
1 Virtual MAC address for each group	1 Virtual MAC address per AVF/AVG in each group
Uses 224.0.0.2 for hello packets.	Uses 224.0.0.102 for hello packets.
Default timers: hello 3 s, holdtime 10 s.	The default timers are shorter in VRRP than HSRP. This often gave VRRP the reputation of being faster than HSRP.
Can track interfaces or objects.	Can track only objects.
Default timers: hello 3 s, holdtime 10 s	Default timers: hello 3 s, holdtime 10 s
Authentication supported	Authentication supported

# GLBP Functions (1)

- **GLBP active virtual gateway (AVG):** Members of a GLBP group elect one gateway to be the AVG for that group. Other group members provide backup for the AVG if the AVG becomes unavailable. The AVG assigns a virtual MAC address to each member of the GLBP group.
- **GLBP active virtual forwarder (AVF):** Each gateway assumes responsibility for forwarding packets that are sent to the virtual MAC address assigned to that gateway by the AVG. These gateways are known as AVFs for their virtual MAC address.
- **GLBP communication:** GLBP members communicate between each other through hello messages sent every 3 seconds to the multicast address 224.0.0.102, User Datagram Protocol (UDP) port 3222.

# GLBP Functions (2)

- Router A is acting as the AVG. Router A has assigned virtual MAC 0007.b400.0101 to itself.
- Router B is acting as AVF for the virtual MAC 0007.b400.0102 assigned to it by Router A.
- Client 1 default gateway is Router A.
- Client 2 default gateway is Router B based on the virtual MAC assignment.

# GLBP Features

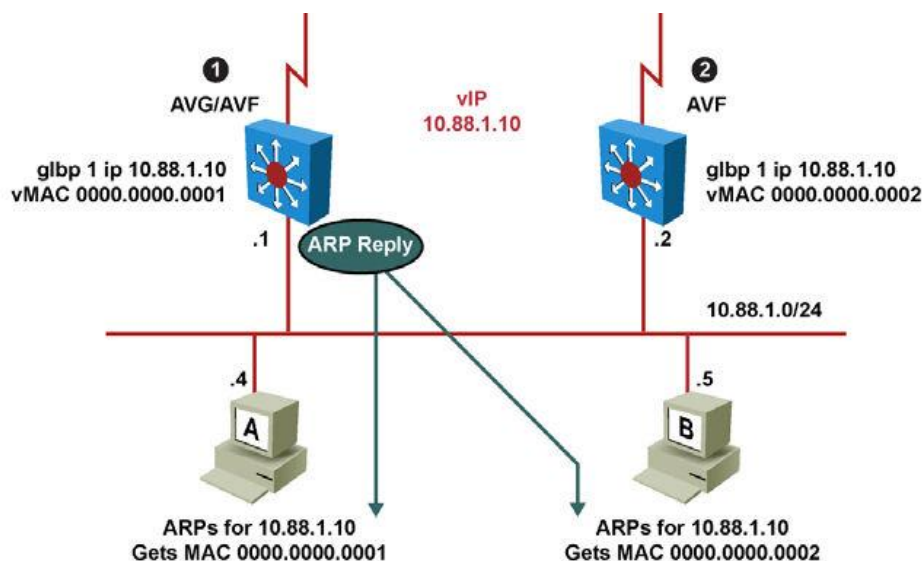

- **Load sharing:** You can configure GLBP in such a way that multiple routers can share traffic from LAN clients, thereby sharing the traffic load more equitably among available routers.
- **Multiple virtual routers:** GLBP supports up to 1024 virtual routers (GLBP groups) on each physical interface of a router and up to four virtual forwarders per group.
- **Preemption:** The redundancy scheme of GLBP enables you to preempt an AVG with a higher priority backup virtual gateway that has become available. Forwarder preemption works in a similar way, except that forwarder preemption uses weighting instead of priority and is enabled by default.
- **Efficient resource utilization:** GLBP makes it possible for any router in a group to serve as a backup, which eliminates the need for a dedicated backup router because all available routers can support network traffic.

# GLBP Operations (1)

Operational modes for load balancing:

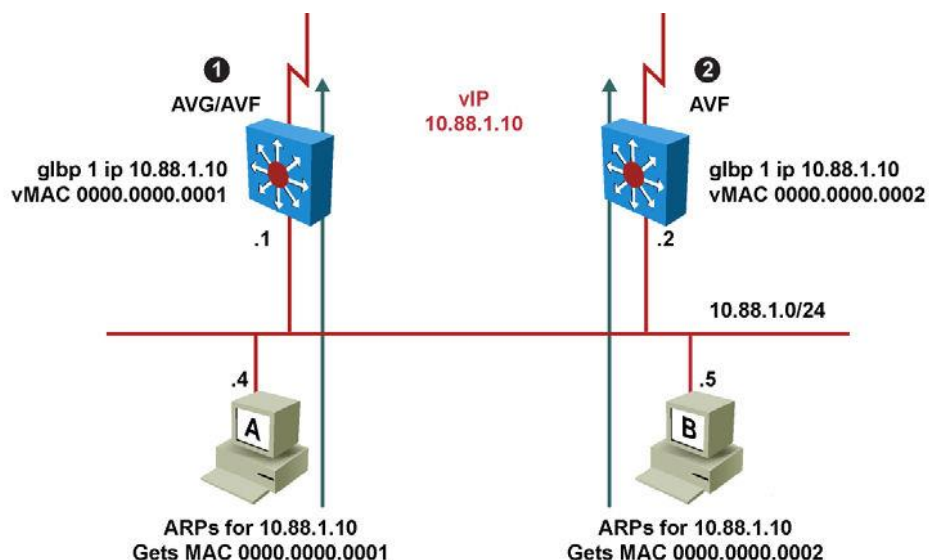

- **Weighted load-balancing algorithm:** The amount of load directed to a router is dependent upon the weighting value advertised by that router.
- **Host-dependent load-balancing algorithm:** A host is guaranteed use of the same virtual MAC address as long as that virtual MAC address is participating in the GLBP group.
- **Round-robin load-balancing algorithm:** As clients send ARP requests to resolve the MAC address of the default gateway, the reply to each client contains the MAC address of the next possible router in round-robin fashion. All routers' MAC addresses take turns being included in address resolution replies for the default gateway IP address.

# GLBP Operations (2)

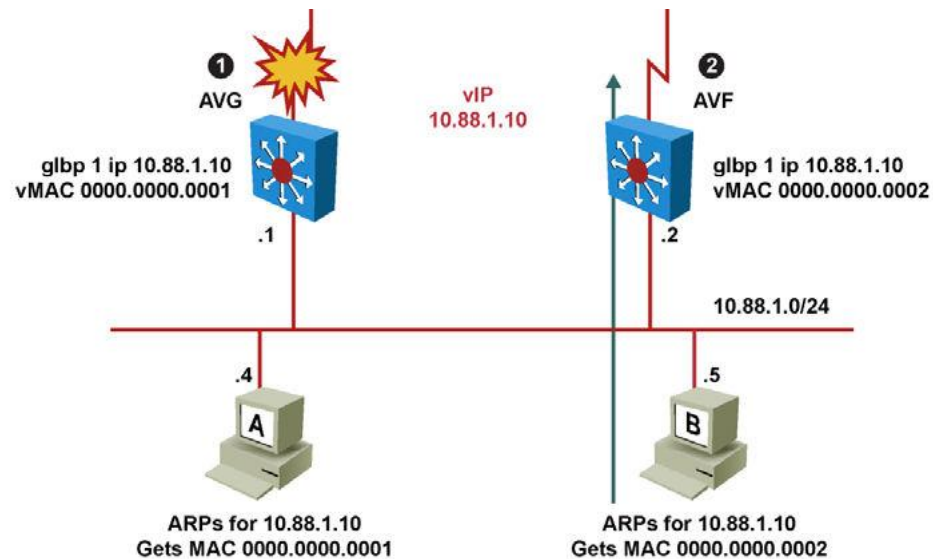

- By default, GLBP attempts to balance traffic on a per-host basis using the round-robin algorithm.
- When a client sends an ARP message for the gateway IP address, the AVG returns the virtual MAC address of one of the AVFs.
- When a second client sends an ARP message, the AVG returns the next virtual MAC address from the list.

# GLBP Operations (3)

- Having each resolved a different MAC address for the default gateway, Clients A and B send their routed traffic to separate routers, although they both have the same default gateway address configured.
- Each GLBP router is an AVF for the virtual MAC address to which it has been assigned.

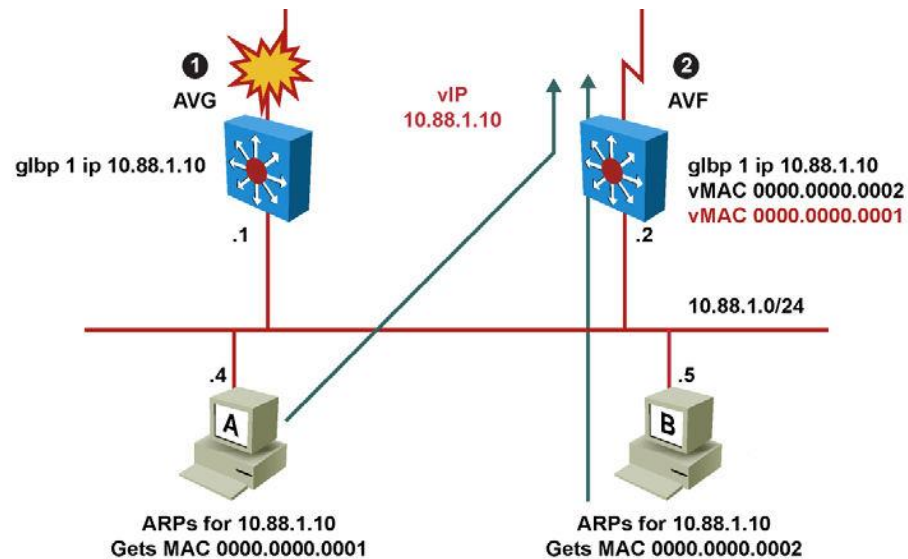

# GLBP Interface Tracking (1)

- Like HSRP, GLBP can be configured to track interfaces.
- The WAN link from Router R1 is lost. GLBP detects the failure. Just like HSRP, GLBP decrements the gateway priority when a tracked interface fails. The second gateway then becomes primary. This transition is transparent for the LAN client.

# GLBP Interface Tracking (2)

- Because interface tracking was configured on R1, the job of forwarding packets for virtual MAC address 0000.0000.0001 will be taken over by the secondary virtual forwarder for the MAC, Router R2. Therefore, the client sees no disruption of service nor does the client need to resolve a new MAC address for the default gateway.

# GLBP Interface Tracking (3)

- SW4 is forwarding. Its initial weight (or priority) is 110.
- SW4 tracks both Fa0/23 and Fa0/24 interfaces. Fa0/23 is the active interface. Losing fa0/23 decrements SW4 by 20 points, thus bringing SW4's weight down (from 110) to 90. Fa0/24 is a backup interface.
- Losing Fa0/24 decrements SW4 by 10 points, thus bringing SW4's weight down (from 110) to 100, which is the default weight of the other routers.
- Losing both Fa0/23 and Fa0/24 brings SW4's weight down (from 110) to 80.

# GLBP Interface Tracking (4)

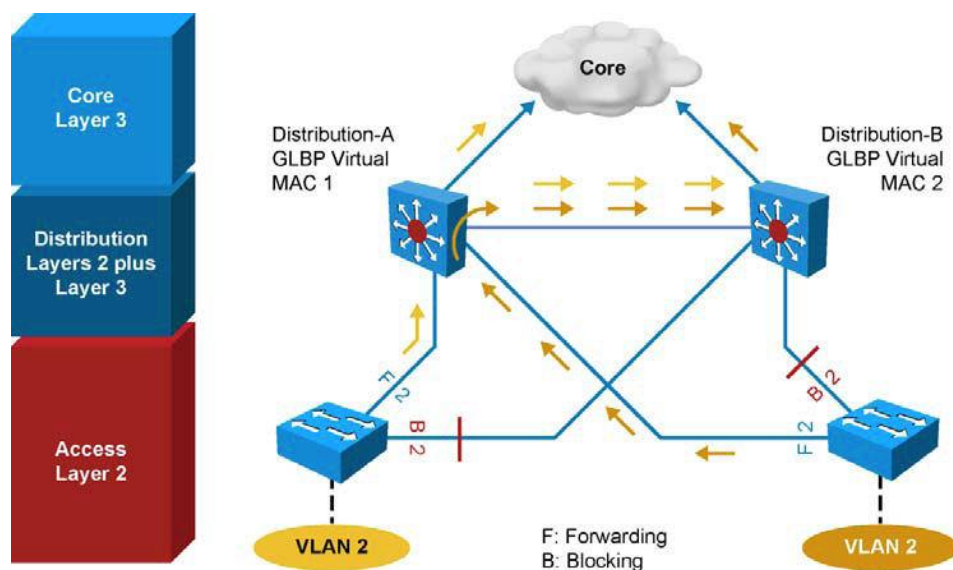

```

SW4(config)# track 90 interface fa0/24 line-protocol
SW4(config)# track 91 interface fa0/23 line-protocol
SW4(config)# interface vlan10
SW4(config-if)# ip address 10.1.10.2 255.255.255.0
SW4(config-if)# glbp 1 10.1.10.1
SW4(config-if)# glbp 1 weighting 110 lower 85 upper 105
SW4(config-if)# glbp 1 timers msec 200 msec 700
SW4(config-if)# glbp 1 preempt delay minimum 300
SW4(config-if)# glbp 1 authentication md5 keystring xyz123
SW4(config-if)# glbp 1 weighting track 90 decrement 10
SW4(config-if)# glbp 1 weighting track 91 decrement 20
    
```

# Configuring GLBP

Step	Description
1.	<p>Enable GLBP on an interface. This command makes the interface a member of the virtual group identified with the IP virtual address:</p> <pre>Switch(config-if)#<b>glbp</b> group-number <b>ip</b> virtual-gateway-address</pre>
2.	<p>Set a GLBP priority for this router for this GLBP group. The highest value wins election as active router. The default is 100. If routers have the same GLBP priority, the gateway with the highest real IP address becomes the AVG:</p> <pre>Switch(config-if)#<b>glbp</b> group-number <b>priority</b> priority-value</pre>
3.	<p>Change timer values for hello interval and holdtime. Place the argument msec before the values to enter subsecond values:</p> <pre>Switch(config-if)#<b>glbp</b> group-number <b>timers</b> hello holdtime</pre>

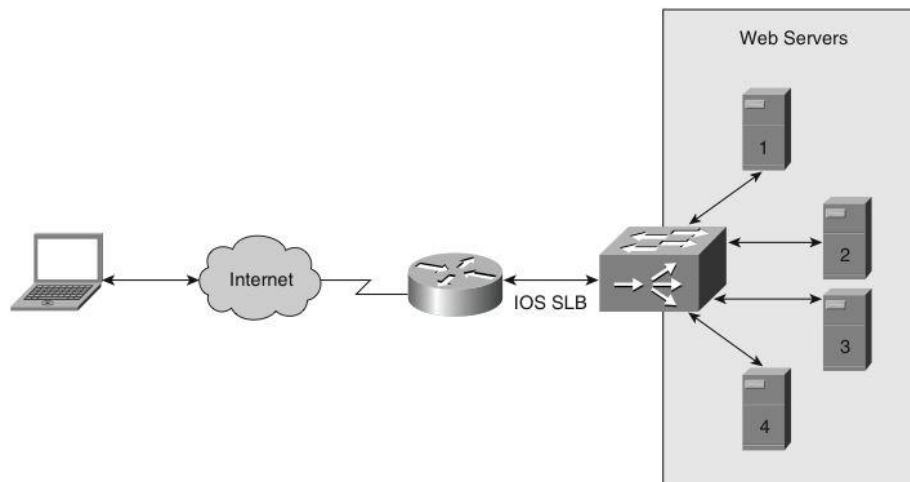

# GLBP with VLAN Spanning Access Switches

- Although invisible and transparent to VLAN 2 clients, the STP blocking state on the access uplink results in the frames coming from VLAN 2 transiting through Distribution A and then through Distribution B before being sent to the core.
- In environments in which VLANs span across access switches, HSRP is the recommended first hop redundancy protocol implementation. In all cases, the active gateway should be configured to also be the root bridge for the VLAN in which first hop redundancy is configured.

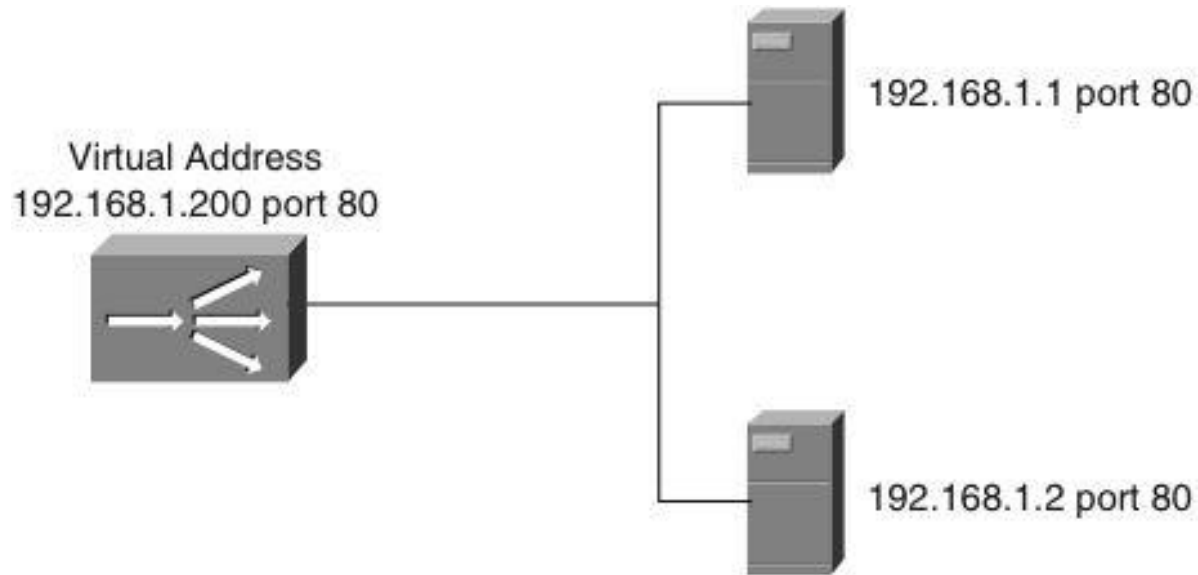

# Cisco IOS Server Load Balancing

# Cisco IOS SLB Benefits

- High performance is achieved through the distribution of client requests across a cluster of servers.
- Administration of server applications is easier. Clients know only about virtual servers; no administration is required for real server changes, making Cisco IOS SLB highly scalable.
- Security of the real server is provided because its address is never announced to the external network. Users are familiar only with the virtual IP address. Additionally, filtering of unwanted traffic can be based on both IP address and IP port numbers.
- Ease of maintenance with no downtime is achieved by allowing physical (real) servers to be transparently placed in or out of service while other servers handle client requests.
- Switches detect servers that are not responding and do not forward further requests to those servers until they begin to respond to polls from the switch.

# SLB Virtual Server and Server Farm

- Cisco IOS SLB enables users to represent a group of network servers (a server farm in a data center) as a single server instance, balance the traffic to the servers, and limit traffic to individual servers. The single server instance that represents a server farm is referred to as a virtual server.
- The graphic above shows Cisco IOS SLB applied to a server farm in a data center. The virtual web server IP address is 192.168.1.200 on port 80, and the real web servers are 192.168.1.1 and 192.168.1.2.
- Any request to the virtual web server address is served by the two real servers.

# Cisco IOS SLB Modes of Operation

Cisco IOS SLB supports the following redirection modes:

- **Dispatched mode:** Each of the real servers is configured with the virtual server address as a loopback address or secondary IP address. Cisco IOS SLB redirects packets to the real servers at the MAC layer. Because the virtual server IP address is not modified in dispatched mode, the real servers must be Layer 2–adjacent to Cisco IOS SLB or intervening routers might not route to the chosen real server.
- **Directed mode:** The virtual server can be assigned an IP address that is not known to any of the real servers in a data center. Cisco IOS SLB translates packets exchanged between a client and a real server, translating the virtual server IP address to a real server address via Network Address Translation (NAT). For more information about Cisco IOS SLB support of different NAT types, refer to the Cisco IOS SLB configuration section of the Cisco product documentation for the Catalyst 6500 switches.

# Configuring the Server Farm in a Data Center with Real Servers (1)

To configure Cisco IOS SLB in a server farm in a data center with real servers:

- Step 1. Define the server farm:

```
Switch(config)# ip slb serverfarm serverfarm-name
```

- Step 2. Associate the real server with the server farm:

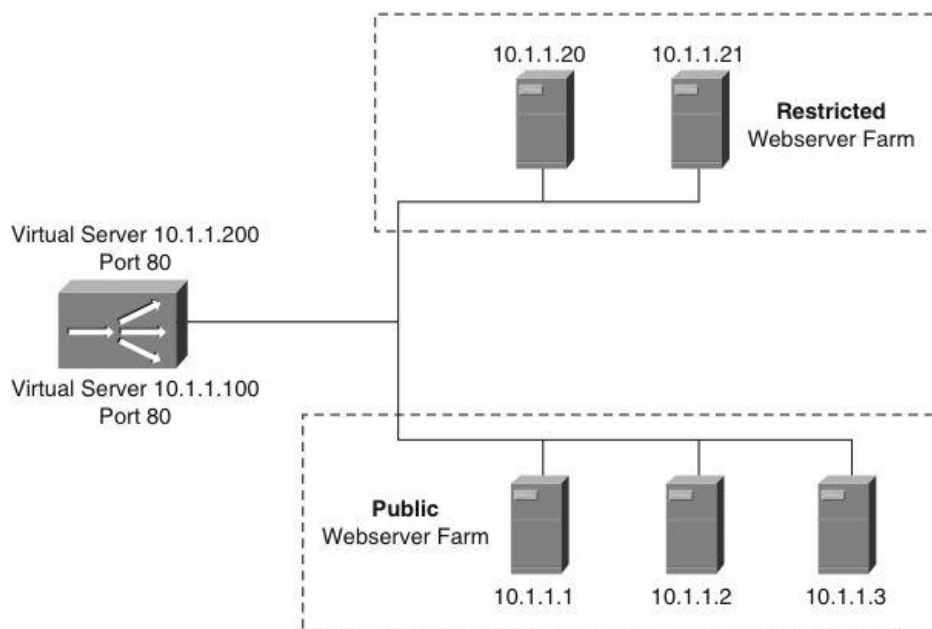

```
Switch(config-slb-sfarm)# real ip-address-of-the-real-server
```

- Step 3. Enable the real server defined to be used for the Cisco IOS server farm:

```
Switch(config-slb-real)# inervice
```

# Configuring the Server Farm in a Data Center with Real Servers (2)

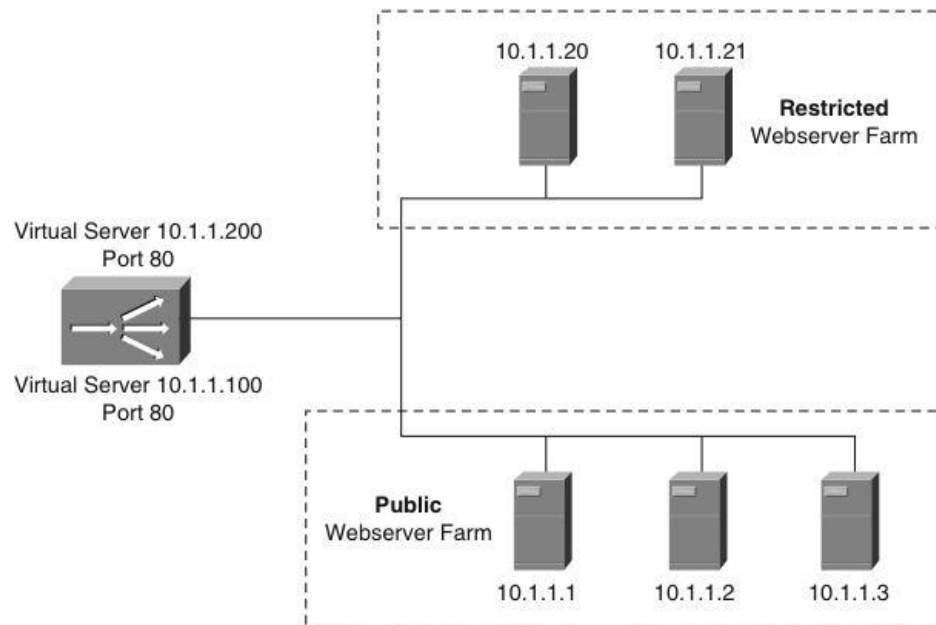

- Two server farms in a data center, PUBLIC and RESTRICTED, are configured.
- The PUBLIC server farm has associated with it three real servers: 10.1.1.1, 10.1.1.2, and 10.1.1.3.
- The RESTRICTED server farm has two real servers associated with it: 10.1.1.20 and 10.1.1.21.

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip slb serverfarm PUBLIC
Switch(config-slb-sfarm)# real 10.1.1.1
Switch(config-slb-real)# inservice
Switch(config-slb-real)# exit
Switch(config-slb-sfarm)# real 10.1.1.2
Switch(config-slb-real)# inservice
Switch(config-slb-real)# exit
Switch(config-slb-sfarm)# real 10.1.1.3
Switch(config-slb-real)# inservice
Switch(config-slb-real)# exit
Switch(config-slb-sfarm)# exit
```

# Configuring the Server Farm in a Data Center with Real Servers (3)

- Two server farms in a data center, PUBLIC and RESTRICTED, are configured.
- The PUBLIC server farm has associated with it three real servers: 10.1.1.1, 10.1.1.2, and 10.1.1.3.
- The RESTRICTED server farm has two real servers associated with it: 10.1.1.20 and 10.1.1.21.

```
Switch(config)# ip slb serverfarm RESTRICTED
Switch(config-slbfarm)# real 10.1.1.20
Switch(config-slbfarm-real)# inservice
Switch(config-slbfarm-real)# exit
Switch(config-slbfarm)# real 10.1.1.21
Switch(config-slbfarm-real)# inservice
Switch(config-slbfarm-real)# end
```

# Configuring the Server Farm in a Data Center with Real Servers (4)

- Displaying the status and configuration of the server farms PUBLIC and RESTRICTED, the associated real servers, and their status.

```
Switch# show ip slb real
real          farm name          weight  state          cons
-----
10.1.1.1      PUBLIC                8       OPERATIONAL    0
10.1.1.2      PUBLIC                8       OPERATIONAL    0
10.1.1.3      PUBLIC                8       OPERATIONAL    0
10.1.1.20     RESTRICTED            8       OPERATIONAL    0
10.1.1.21     RESTRICTED            8       OPERATIONAL    0
Switch# show ip slb serverfarm
server farm   predictor    nat    reals    bind id
-----

RESTRICTED    ROUNDROBIN   none   2        0
```

# Configuring the Server Farm in a Data Center with Virtual Servers (1)

To configure Cisco IOS SLB in a server farm in a data center with virtual servers:

**Step 1.** Define the virtual server:

```
Switch(config)# ip slb vserver vserver-name
```

**Step 2.** Configure the IP address of the virtual server:

```
Switch(config-slb-vserver)# virtual ip-address [network-mask] {tcp  
| udp} [port-number | wsp | wsp-wtp | wsp-wtls | wsp-wtp-wtls]  
[service service-name]
```

**Step 3.** Associate the primary and secondary server farm to the virtual server:

```
Switch(config-slb-vserver)# serverfarm primary-serverfarm-name  
[backup backup-serverfarm-name [sticky]]
```

**Step 4.** Enable the virtual server:

```
Switch(config-slb-vserver)# inservice
```

**Step 5.** Specify the clients allowed to access the virtual server:

```
Switch(config-slb-vserver)# client ip-address network-mask
```

# Configuring the Server Farm in a Data Center with Virtual Servers (2)

Configuring the virtual servers PUBLIC\_HTTP and RESTRICTED\_HTTP and restricting access to RESTRICTED\_HTTP to clients in the network 10.4.4.0.

```
Switch(config)# ip slb vserver PUBLIC_HTTP
Switch(config-slb-vserver)# virtual 10.1.1.100 tcp www
Switch(config-slb-vserver)# serverfarm PUBLIC
Switch(config-slb-vserver)# inservice
Switch(config-slb-vserver)# exit
Switch(config)# ip slb vserver RESTRICTED_HTTP
Switch(config-slb-vserver)# virtual 10.1.1.200 tcp www
Switch(config-slb-vserver)# client 10.4.4.0 255.255.255.0
Switch(config-slb-vserver)# serverfarm RESTRICTED
Switch(config-slb-vserver)# inservice
Switch(config-slb-vserver)# end
```

# Configuring the Server Farm in a Data Center with Virtual Servers (3)

- Verifying the configuration of the virtual servers PUBLIC\_HTTP and RESTRICTED\_HTTP with the **show ip slb vserver** command.
- Verifying the restricted client access and status with the **show ip slb connections** command.

```
Switch# show ip slb vserver
```

slb vserver	prot	virtual	state	cons
PUBLIC_HTTP	TCP	10.1.1.100:80	OPERATIONAL	0
RESTRICTED_HTTP	TCP	10.1.1.200:80	OPERATIONAL	0

```
Switch# show ip slb connections
```

vserver	prot	client	real	state	nat
RESTRICTED_HTTP	TCP	10.4.4.0:80	10.1.1.20	CLOSING	none

# Configuring the Server Farm in a Data Center with Virtual Servers (3)

- Displaying detailed information about the restricted client access status with the **show ip slb connections client** command.
- Displaying information about the Cisco IOS SLB network statistics with the **show ip slb stats** command.

```
Switch# show ip slb connections client 10.4.4.0 detail
VSTEST_UDP, client = 10.4.4.0:80
state = CLOSING, real = 10.1.1.20, nat = none
v_ip = 10.1.1.200:80, TCP, service = NONE
client_syns = 0, sticky = FALSE, flows attached = 0
```

```
Switch# show ip slb stats
Pkts via normal switching: 0
Pkts via special switching: 6
Connections Created: 1
Connections Established: 1
Connections Destroyed: 0
Connections Reassigned: 0
Zombie Count: 0
Connections Reused: 0
```

# Chapter 5 Summary (1)

- Building a resilient and highly available network is paramount as most organizations depend on the network for the business operations.
- High availability involves several elements: redundancy, technology, people, processes and tools. At the network level, high availability involves making sure that there is always a possible path between two endpoints. High availability minimizes link and node failures to minimize downtime by implementing link and node redundancy, providing alternate paths for traffic, and avoiding single points of failure.
- Redundancy is a balance between too much redundancy, which increases complexity in the network structure, and too little redundancy, which creates single points of failure. When uplinks fail, convergence paths and convergence time have to be taken into account to evaluate the impact of the failure on the network infrastructure.

# Chapter 5 Summary (2)

- On Cisco IOS-based Catalyst switches, RPR, RPR+, SSO, and NSF with SSO are the various modes of Supervisor redundancy available. The preferred mode is the NSF with SSO because it provides both Layer 2 and Layer 3 protocol state synchronization between active and standby Supervisors, therefore guaranteeing the least amount of network impact due to failover, if any at all.
- Various first hop redundancy protocols (FHRP) exist including HSRP, VRRP, and GLBP. Currently, HSRP is the most popular choice.
- HSRP operates with one router acting as active and the other backup router as a standby router. The active, standby, and other HSRP routers use a virtual IP address for redundancy to hosts. If the active router fails, the standby router becomes the active router and takes responsibility of the destination MAC and IP of the virtual IP address. In this manner, HSRP failover is transparent to the host. Routers running HSRP can be configured for preemption such that if a higher-priority HSRP peer comes online, the higher-priority router takes over the active router role. Otherwise, the latest active router remains the active router when new HSRP peers come online.

# Chapter 5 Summary (3)

- VRRP is similar to HSRP except that VRRP is an industry standard, whereas HSRP is a Cisco-proprietary protocol. GLBP is a Cisco-proprietary FHRP in which multiple routers not only act as backup default gateway routers but also share load in forwarding traffic, unlike HSRP and VRRP, where only the active router forwards traffic. Note that HSRP and VRRP can be distributed across VLANs, manually achieving load balancing using VLANs.
- The Cisco IOS SLB features enable load balancing of connections to a group of real servers and therefore provides fault tolerance for the group of real servers. With this feature, hosts connect to a single virtual server, which in turn is supported by many real servers that are transparent to the host. IOS SLB supports many forms of load balancing and redundancy.
- Monitoring the network using SNMP, Syslog, and IP SLA are key elements to ensuring high availability of the network and to taking corrective action when necessary to ensure increased availability.

# Chapter 4 Labs

- **SW-LAB-2.3**
  - VRRP-HSRP
  
- **SW-LAB-2.4**
  - GLBP
